# ABSTRACT <br> On Orthogonal Matrices <br> Majid Behbahani <br> Department of Mathematics and Computer Science <br> University of Lethbridge <br> M. Sc. Thesis, 2004 

Our main aim in this thesis is to study and search for orthogonal matrices which have a certain kind of block structure. The most desirable class of matrices for our purpose are orthogonal designs constructible from 16 circulant matrices. In studying these matrices, we show that the $O D(12 ; 1,1,1,9)$ is the only orthogonal design constructible from 16 circulant matrices of type $O D(4 n ; 1,1,1,4 n-3)$, whenever $n>1$ is an odd integer. We then use an exhaustive search to show that the only orthogonal design constructible from 16 circulant matrices of order 12 on 4 variables is the $O D(12 ; 1,1,1,9)$. It is known that by using of $T$-matrices and orthogonal designs constructible from 16 circulant matrices one can produce an infinite family of orthogonal designs. To complement our studies we reproduce an important recent construction of $T$-matrices by Xia and Xia.

We then turn our attention to the applications of orthogonal matrices. In some recent works productive regular Hadamard matrices are used to construct many new infinite families of symmetric designs. We show that for each integer $n$ for which $4 n$ is the order of a Hadamard matrix and $8 n^{2}-1$ is a prime, there is a productive regular Hadamard matrix of order $16 n^{2}\left(8 n^{2}-1\right)^{2}$. As a corollary, we get many new infinite classes of symmetric designs whenever either of $4 n\left(8 n^{2}-1\right)-1,4 n\left(8 n^{2}-1\right)+1$ is a prime power. We also review some other constructions of productive regular Hadamard matrices which are related to our work.

To My Parents

## ACKNOWLEDGEMENTS

First I would like to thank my family for always supporting me.

I would like to extend my warmest gratitude to my supervisor, Dr. Hadi Kharaghani, for his immense amount of support, advice, and guidance throughout the process. I couldn't have done any of this without his support.

Acknowledgement also needs to be extended to my co-supervisor, Dr. Wolf Holzmann, for his constant help and continued support.

My special thanks also to the members of my defence committee, Dr. Saurya Das, Dr. Wolf Holzmann, Dr. Yury J. Ionin, Dr. Hadi Kharaghani, and Dr. Mark Walton, for their valuable comments, suggestions, and corrections.

I am grateful to Dr. Amir Akbary for his helpful conversations and valuable suggestions. His help is greatly appreciated.

I also acknowledge Dr. Hadi Kharaghani as well as the university of Lethbridge for supporting me financially.

I am grateful to Sean Legge and Stephen Ney for doing the proofreading and providing helpful suggestions.

## Chapter 1

## Introduction and statements of results

Definition 1.1 A Hadamard matrix $H$ of order $n$ is an $n \times n$ matrix with $\pm 1$ entries such that: $H H^{t}=n I_{n}$, where $I_{n}$ is the identity matrix of order $n$.

The order of a Hadamard matrix must be 1,2 or a multiple of 4 . The conjecture that all Hadamard matrices of order $4 n$ exist for every positive integer $n$ is still an important open problem. One way to generalise Hadamard matrices is by means of orthogonal designs.

Definition 1.2 An orthogonal design $A$ of order $n$ and type $u_{1}, \ldots, u_{t}$, where each $u_{i}$ is a positive integer, denoted $O D\left(n ; u_{1}, \ldots, u_{t}\right)$, is an $n \times n$ matrix with entries from $\left\{0, \pm x_{1}, \ldots, \pm x_{t}\right\}$ (the $x_{i}$ commuting indeterminates) satisfying

$$
A A^{t}=\left(\sum_{i=1}^{t} u_{i} x_{i}^{2}\right) I_{n} .
$$

Despite extensive work on the existence and properties of orthogonal designs, not many significant results are known about these matrices. One very useful constructive method for orthogonal designs is by means of $T$-matrices.

Definition 1.3 Four type-1 $\{0, \pm 1\}$ matrices $T_{1}, T_{2}, T_{3}$, and $T_{4}$ of order $n$ are $T$ matrices if they satisfy the following conditions:

1. $T_{i} \cap T_{j}=0$ where $i \neq j$;
2. $\sum_{i=1}^{4}\left|T_{i}\right|=J$;
3. $\sum_{i=1}^{4} T_{i} T_{i}^{t}=n I$.

By combining orthogonal designs constructible from 16 circulant matrices with $T$ matrices one can construct a large family of very useful orthogonal designs. Although there is an orthogonal design of order 20 constructible from 16 circulant matrices, nothing is known about the existence of such matrices of order 12. In chapter 2 we will show that $O D(12 ; 1,1,1,9)$ and $O D(4 ; 1,1,1,1)$ are the only orthogonal designs of type $O D(4 n ; 1,1,1,4 n-3)$ constructible from 16 circulant matrices when $n$ is odd. We also use an exhaustive search to show that $O D(12 ; 1,1,1,9)$ is the only orthogonal design of order 12 on 4 variables constructible from 16 circulant matrices.

The existence of amicable set of $T$-matrices has proven to be instrumental in the construction of orthogonal designs.

Definition 1.4 The $T$-matrices $T_{1}, T_{2}, T_{3}$, and $T_{4}$ of order $n$ are amicable $T$-matrices if they satisfy the amicability condition:

$$
T_{1} T_{2}^{t}-T_{2} T_{1}^{t}+T_{3} T_{4}^{t}-T_{4} T_{3}^{t}=0
$$

(Note that there is no specific order for $T_{i} s$, and we can rename them to satisfy the amicability condition in this order.)

In part of chapter 2 we show that amicable $T$-matrices of odd order do not exist. We then conclude the chapter by a very important recent result concerning finite fields [17]. Our hope is to develop and use this result in the future to produce some positive results on the existence of $T$-matrices.

We devote the remaining chapters to the applications of Hadamard matrices in the construction of symmetric designs.

Definition 1.5 A symmetric ( $v, k, \lambda$ )-design is an incidence system $(P, \mathcal{B})$ in which $P=\left\{p_{1}, p_{2}, \ldots, p_{v}\right\}$ is a set of $v$ points and $\mathcal{B}=\left\{b_{1}, \ldots, b_{v}\right\}$ is a set of $v$ blocks, each block being a $k$-subset of $P$ such that any two points of $P$ are incident with exactly $\lambda$ blocks of $\mathcal{B}$.

Symmetric designs can be expressed by their incidence matrices.
Definition 1.6 The incidence matrix of a symmetric ( $v, k, \lambda$ ) -design is a $v \times v$ matrix $A=\left[a_{i j}\right]$ such that

$$
a_{i j}=\left\{\begin{array}{cc}
1 & \text { if } p_{i} \in b_{j} \\
0 & \text { otherwise }
\end{array}\right.
$$

A ( 0,1 )-matrix $A$ is an incidence matrix of a symmetric ( $v, k, \lambda$ ) design if and only if

$$
A A^{t}=(k-\lambda) I+\lambda J .
$$

In this thesis we only study symmetric designs constructed from productive regular Hadamard matrices. The class of productive Hadamard matrices was defined by Yury Ionin in [4].

A regular Hadamard matrix is a Hadamard matrix with constant row sum.
Definition 1.7 A regular Hadamard matrix $H$ with row sum $2 h$ is productive if there is a set $\mathcal{H}$ of matrices with row sum $2 h$ and a cyclic group $G=<\delta>$ where $\delta: \mathcal{H} \rightarrow \mathcal{H}$ is a bijection, such that

1. $H \in \mathcal{H}$;
2. For any $H_{1}, H_{2} \in \mathcal{H},\left(\delta H_{1}\right)\left(\delta H_{2}\right)^{t}=H_{1} H_{2}^{t}$;
3. $|G|=4|h|$;
4. $\sum_{\boldsymbol{q} \in G} \sigma H=2 \frac{h}{|h|} J$.

Productive Hadamard matrices are normally used in Balanced Generalised Weighing matrices over cyclic groups.

Definition 1.8 Let $G$ be a multiplicatively written group. A balanced generalised weighing matrix $B G W(v, k, \lambda)$ is a matrix $W=\left[w_{i j}\right.$; of order $v$ with $w_{i j} \in G \cup\{0\}$ such that each row and each column of $W$ contains exactly $k$ non-zero entries and such that for any $h \neq i$, the multiset $\left\{w_{h j} w_{i j}^{-1}: 1 \leq j \leq v, w_{h j} \neq 0, w_{i j} \neq 0\right\}$ contains exactly $\lambda /|G|$ copies of every element of $G$.

A large class of balanced generalised weighing matrices of the type

$$
B G W\left(\left(q^{m}-1\right) /(q-1), q^{m-1}, q^{m-1}-q^{m-2}\right)
$$

over a cyclic group $G$, where $q$ is a prime power, $m$ is a positive integer and the order of $G$ divides $q-1$, is known to exist.
A classical construction due to Ionin is as follows:
Theorem 1.9 If there is a productive regular Hadamard matrix $H$ with row sum $2 h$ and if $q=(2 h-1)^{2}$ is a prime power then for any positive integer $m$ there is a symmetric design with parameters:

$$
\left(\frac{4 h^{2}\left(q^{m+1}-1\right)}{q-1},\left(2 h^{2}-h\right) q^{m} ;\left(h^{2}-h\right) q^{m}\right) .
$$

Bush-type Hadamard matrices are all known to be productive.
Definition 1.10 A regular Hadamard matrix $H=\left[H_{i j} j\right.$ of order $4 n^{2}$ where $H_{i j}$ are blocks of order $2 n$ is Bush-type if $H_{i i}=J_{2 n}$ and $H_{i j} J_{2 n}=J_{2 n} H_{i j}=0$, for $i \neq j$, $1 \leq i, j \leq 2 n$.

The class of Bush-type Hadamard matrices is the largest class of productive regular Hadamard matrices that is known to exist. Indeed, it is known that there is a Bushtype Hadamard matrix of order $16 n^{2}$ for all $n$ for which there is a Hadamard matrix of order $4 n$.

In chapter 4 we construct a new class of regular Hadamard matrices by combining the class of Mathon matrices with Bush-type Hadamard matrices and then construct a new family of productive regular Hadamard matrices.

Our main results in chapter 4 are as follows.
Theorem 1.11 If there is a Hadamard matrix of order $4 n$ and $m=8 n^{2}-1$ is prime then there is a productive regular Hadamard matrix of order $16 n^{2} m^{2}$.

Corollary 1.12 If $m=8 n^{2}-1$ is prime and if $q=(4 n m-1)^{2}$ is a prime power then there is a symmetric design with parameters:

$$
\left(16 n^{2} m^{2}\left(q^{t}+q^{t-1}+\cdots+1\right),\left(8 n^{2} m^{2}-2 n m\right) q^{t},\left(4 n^{2} m^{2}-2 n m\right) q^{t}\right)
$$

for any positive integer $t$. Likewise if $q=(4 n m+1)^{2}$ is a prime power then there is a symmetric design with parameters:

$$
\left(16 n^{2} m^{2}\left(q^{t}+q^{t-1}+\cdots+1\right),\left(8 n^{2} m^{2}+2 n m\right) q^{t},\left(4 n^{2} m^{2}+2 n m\right) q^{t}\right)
$$

for any positive integer $t$.

## Chapter 2

## Orthogonal matrices

### 2.1 Orthogonal designs

This chapter will be devoted to orthogonal matrices and more specifically to orthogonal designs. We begin with the definition of two important classes of matrices. We will follow Geramita and Seberry [3] for the following definition and lemma:

Definition 2.1 Let $G$ be an additive abelian group of order $t$, order the elements of $G$ as $z_{1}, \ldots, z_{i}$ and let $\Psi$ and $\Phi$ be two functions from $G$ into a commutative ring. We define two matrices $M=\left[m_{i j}\right]$ and $N=\left[n_{i j}\right]$ of order $t$ as follows:

$$
m_{i j}=\Psi\left(z_{j}-z_{i}\right) \text { and } n_{i j}=\Phi\left(z_{j}+z_{i}\right)
$$

$M$ and $N$ are called type-1 and type-2 matrices respectively on the group $G$.
Lemma 2.2 If $X$ and $Y$ are type- -1 matrices and $Z$ is a type-2 matrix on an abelian group $G$ of order $n$ with elements ordered $z_{1}, \ldots, z_{n}$, and $R=\left[r_{i j}\right]$ is defined as:

$$
r_{i j}=\left\{\begin{array}{cc}
1 & \text { if } z_{i}+z_{j}=0 \\
0 & \text { otherwise }
\end{array}\right.
$$

then:

- $X Y=Y X$;
- $Z^{t}=Z$;
- $X Z^{t}=Z X^{t}$;
- $X^{t}$ is a type- 1 matrix;
- $X+Y$ and $X-Y$ are type -1 matrices;
- $X R$ is a type-2 matrix and $Z R$ is a type-1 matrix.

Definition 2.3 Matrices $A$ and $C$ of order $n$ are circulant and back-circulant matrices if they are type-1 and type-2 matrices, respectively, on the cyclic group $Z_{n}$.

Example 1. $A$ is a circulant matrix of order 5 and $C$ is a back circulant matrix of order 5 , where

$$
A=\left[\begin{array}{lllll}
a & b & c & d & e \\
e & a & b & c & d \\
d & e & a & b & c \\
c & d & e & a & b \\
b & c & d & e & a
\end{array}\right] \quad, \quad C=\left[\begin{array}{lllll}
a & b & c & d & e \\
b & c & d & e & a \\
c & d & e & a & b \\
d & e & a & b & c \\
e & a & b & c & d
\end{array}\right]
$$

Definition 2.4 Four type-1 $\{0, \pm 1\}$ matrices $T_{1}, T_{2}, T_{3}$, and $T_{4}$ of order $n$ are $T$ matrices if they satisfy the following conditions:
(i) $T_{i} \cap T_{j}=0$;
(ii) $\sum_{i}\left|T_{i}\right|=J$;
(iii) $\sum_{i} T_{i} T_{i}^{t}=n I$.

Example 2. Matrices $T_{1}, T_{2}, T_{3}$, and $T_{4}$ are circulant $T$-matrices of order 3 .

$$
T_{1}=\left[\begin{array}{lll}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{array}\right], \quad T_{2}=\left[\begin{array}{lll}
0 & 1 & 0 \\
0 & 0 & 1 \\
1 & 0 & 0
\end{array}\right], \quad T_{3}=\left[\begin{array}{lll}
0 & 0 & 1 \\
1 & 0 & 0 \\
0 & 1 & 0
\end{array}\right], \quad T_{4}=\left[\begin{array}{lll}
0 & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0
\end{array}\right]
$$

Definition 2.5 An orthogonal design of order $n$ and type $s_{1}, \ldots, s_{l}$, where $s_{i}$ are positive integers denoted $O D\left(n ; s_{1}, \ldots, s_{l}\right)$, is an $n \times n$ matrix $A$ with entries from $\left\{0, \pm x_{1}, \ldots, \pm x_{l}\right\}$ (the $x_{i}$ commuting indeterminates) satisfying

$$
A A^{t}=\left(\sum_{i=1}^{l} s_{i} x_{i}^{2}\right) I_{n}
$$

There are several ways to construct orthogonal designs; one way is to use four circulant or type-1 matrices in the Goethals-Seidel array as follows.

Theorem 2.6 Suppose there exist four circulant (type-1) matrices $A, B, C$, and $D$ of order $n$ with entries from the set $\left\{0, \pm x_{1}, \ldots, \pm x_{t}\right\}$ and suppose further that

$$
A A^{t}-B B^{t}+C C^{t}+D D^{t}=\sum_{i=1}^{t} s_{i} x_{i}^{2} I_{n}
$$

Let, $R$ be the back-diagonal (equivalent type-2) matrix of order $n$. Then

$$
\left(\begin{array}{cccc}
A & B R & C R & D R  \tag{2.1}\\
-B R & A & D^{t} R & -C^{t} R \\
-C R & -D^{t} R & A & B^{t} R \\
-D R & C^{t} R & -B^{t} R & A
\end{array}\right)
$$

is an $O D\left(4 n ; s_{1}, \ldots, s_{t}\right)$.
A method to produce the proper matrices $A, B, C$ : and $D$ to be plugged into a Goethals-Scidel array is to use $T$-matrices and orthogonal designs constructible from 16 circulant matrices. Turyn [15), was the first to use $T$-matrices and orthogonal designs constructible from 16 circulant blocks to construct new orthogonal designs.

Theorem 2.7 If there is an $O D\left(4 s ; u_{1}, \ldots, u_{n}\right)$ constructible from 16 circulant $s \times s$ blocks in variables $x_{1}, \ldots, x_{n}$ and there are $T$-matrices of order $t$, then there is an $O D\left(4 s t ; t u_{1}, \ldots, t u_{n}\right)$.

Proof Let

$$
P=\left[\begin{array}{llll}
P_{11} & P_{12} & P_{13} & P_{14} \\
P_{21} & P_{22} & P_{23} & P_{24} \\
P_{31} & P_{32} & P_{33} & P_{34} \\
P_{41} & P_{42} & P_{43} & P_{44}
\end{array}\right]
$$

be an $O D\left(4 n ; u_{1}, \ldots, u_{n}\right)$ constructible from 16 circulant matrices $P_{i j}, 1 \leq i, j \leq 4$. We have

$$
P_{i 1} P_{j 1}^{t}+P_{i 2} P_{j 2}^{t}+P_{i 3} P_{j 3}^{t}+P_{i 4} P_{j 4}^{t}= \begin{cases}\sum_{k=1}^{n} u_{k} x_{k}^{2}, & i=j ; \\ 0, & i \neq j\end{cases}
$$

Suppose that $T_{1}, T_{2}, T_{3}$, and $T_{4}$ are $T$-matrices of order $t$. Let

$$
\begin{aligned}
& A=T_{1} \otimes P_{11}+T_{2} \otimes P_{21}+T_{3} \otimes P_{31}+T_{4} \otimes P_{41}, \\
& B=T_{1} \otimes P_{12}+T_{2} \otimes P_{22}+T_{3} \otimes P_{32}+T_{4} \otimes P_{42}, \\
& C=T_{1} \otimes P_{13}+T_{2} \otimes P_{23}+T_{3} \otimes P_{33}+T_{4} \otimes P_{43}, \\
& D=T_{1} \otimes P_{14}+T_{2} \otimes P_{24}+T_{3} \otimes P_{34}+T_{4} \otimes P_{44} .
\end{aligned}
$$

It is easy to see that

$$
A A^{t}+B B^{t}+C C^{t}+D D^{t}=\sum_{k=1}^{n} t u_{k} x_{k}^{2} I_{s t}
$$

and $A, B, C$, and $D$ are type-1 matrices. Thus they can be plugged into a GoethalsSeidel array to give an $O D\left(4 s t ; t u_{1}, \ldots, t u_{n}\right)$.

Despite the fact that there is a Welch array of order 20 constructible from 16 circulant matrices and an Ono-Sawade-Yumamoto array of order 36 constructible from 16 block circulant matrices [14], nothing similar is known for order 12. We will first study and settle the case for order 12 .

The following orthogonal design is an $O D(12 ; 1,1,1,9)$ constructible from 16 circulant matrices.
$\left[\begin{array}{llllllllllll}\eta & \eta & \eta & a & \bar{\eta} & \eta & b & \bar{\eta} & \eta & c & \bar{\eta} & \eta \\ \eta & \eta & \eta & \eta & a & \bar{\eta} & \eta & b & \bar{\eta} & \eta & c & \bar{\eta} \\ \eta & \eta & \eta & \bar{\eta} & \eta & a & \bar{\eta} & \eta & b & & \bar{\eta} & \eta\end{array}\right)$

We will first show that $O D(12 ; 1,1,1,9)$ and the trivial $O D(4 ; 1,1,1,1)$ are the only orthogonal designs of type $O D(4 n ; 1,1,1,4 n-3)$ constructible from 16 circulant matrices whenever $n$ is an odd number. We will then show, by an exhaustive computer search, that this $O D(12 ; 1,1,1,9)$ is the only orthogonal design in four variables constructible from 16 circulant matrices.

Theorem 2.8 If $n$ is an odd number then $O D(12 ; 1,1,1,9)$ and $O D(4,1,1,1,1)$ are the only orthogonal designs of the form $O D(4 n ; 1,1,1,4 n-3)$ constructible from 16 circulant matrices.

Proof Let

$$
P=\left(\begin{array}{llll}
P_{11} & P_{12} & P_{13} & P_{14}  \tag{2.2}\\
P_{21} & P_{22} & P_{23} & P_{24} \\
P_{31} & P_{32} & P_{33} & P_{34} \\
P_{41} & P_{42} & P_{43} & P_{44}
\end{array}\right)
$$

be an $O D(4 n ; 1,1,1,4 n-3)$ constructible from 16 circulant matrices $P_{i j}, 1 \leq i, j \leq 4$. Let $a, b, c$ be the variables that appear once in each row (and column) of $P$ and let $\eta$
be the variable that appears $4 n-3$ times in each row. We have

$$
\begin{equation*}
\sum_{1 \leq j \leq 4} P_{i j} P_{i j}^{t}=\left(a^{2}+b^{2}+c^{2}+(4 n-3) \eta^{2}\right) I, \quad 1 \leq i \leq 4 \tag{2.3}
\end{equation*}
$$

and

$$
\begin{equation*}
\sum_{1 \leq j \leq 4} P_{i j} P_{k j}^{l}=0, \quad 1 \leq i, k \leq 4, \quad i \neq k \tag{2.4}
\end{equation*}
$$

Since $P_{i j}$ is a circulant matrix satisfying (2.3), each of $a, b$, or $c$ can appear only in one block $P_{i j}$. For convenience we will denote the block containing $x$ by $X_{l}$, and call it $x$-type, for $x \in\{a, b, c\}$. The block whose entries are only $\pm \eta$ will be called $\eta$-type. So the matrix $P$ in the new notation is of the form:

$$
P=\left(\begin{array}{cccc}
M_{1} & A_{1} & B_{1} & C_{1}  \tag{2.5}\\
A_{2} & -M_{2} & -C_{2} & B_{2} \\
-B_{3} & -C_{3} & M_{3} & A_{3} \\
C_{4} & -B_{4} & A_{4} & -M_{4}
\end{array}\right)
$$

where each $A_{i}, B_{i}, C_{i}, M_{i}$ is an $a, b, c, \eta$-type matrix respectively. Since $A_{i}, B_{i}$, and $C_{i}$ are circulant matrices, by shifting the rows or columns we can always put the variables $a, b$, and $c$ on the diagonal of the corresponding matrix and then the matrix will be called a diagonal matrix. By column permutations on block columns 2,3 , and 4 of the matrix $P$ we can make $A_{1}, B_{1}$, and $C_{1}$ diagonal matrices. By row permutations on block rows 2,3 , and 4 of $P$ we can make $B_{2}, A_{3}$, and $A_{4}$ diagonal matrices and then by column shifts on block row 1 make $A_{2}$ a diagonal matrix. It is easy to see that the fact that $B_{1}, C_{1}$, and $B_{2}$ being diagonal matrices together with condition (2.4) implies that $C_{2}$ is a diagonal matrix. By the same reasoning, $C_{3}, B_{3}, B_{4}$, and $C_{4}$ are diagonal matrices. Because $A_{1}, B_{1}$, and $C_{1}$ are diagonal matrices we have:

$$
M_{1}=M, A_{1}=A=a I+A^{\prime}, B_{1}=B=b I+B^{\prime}, \text { and } C_{1}=C=c I+C^{\prime}
$$

where $A^{\prime}, B^{\prime}$, and $C^{\prime}$ are $\{0, \pm \eta\}$ matrices. Then by (2,3) we have:

$$
\begin{gathered}
M M^{t}+\left(a I+A^{\prime}\right)\left(a I+A^{\prime t}\right)+\left(b I+B^{\prime}\right)\left(b I+B^{\prime t}\right)+\left(c I+C^{\prime}\right)\left(c I+C^{\prime t}\right) \\
=M M^{t}+A^{\prime} A^{\prime t}+B^{\prime} B^{\prime t}+C^{\prime} C^{\prime t}+\left(a^{2}+b^{2}+c^{2}\right) I \\
+a\left(A^{\prime}-A^{\prime t}\right)+b\left(B^{\prime}+B^{\prime t}\right)+c\left(C^{\prime}+C^{\prime t}\right) \\
=\left(a^{2}+b^{2}+c^{2}+(4 n-3) \eta^{2}\right) I,
\end{gathered}
$$

so we get $A^{\prime t}=-A^{\prime}, B^{\prime t}=-B^{\prime}$, and $C^{\prime t}=-C^{\prime}$ and also

$$
\begin{equation*}
M M^{t}-A^{\prime 2}-B^{\prime 2}-C^{\prime 2}=(4 n-3) \eta^{2} I \tag{2.6}
\end{equation*}
$$

As $A_{2}, B_{2}$, and $C_{2}$ are diagonal matrices we can write $A_{2}=a I+A_{2}^{\prime}, B_{2}=b I+B_{2}^{\prime}$, and $C_{2}=c I+C_{2}^{\prime}$ where $A_{2}^{\prime}, B_{2}^{\prime}$; and $C_{2}^{\prime}$ are $\{0, \pm \eta\}$ matrices. Considering block rows 1 and 2 , by (2.4) we can write

$$
\begin{align*}
M A_{2}^{t}-A M_{2}^{t}-B C_{2}^{t}+C B_{2}^{t}= & M\left(a I+A_{2}^{\prime t}\right)-\left(a I+A^{\prime}\right) M_{2}^{t} \\
& -\left(b I+B^{\prime}\right)\left(c I+C_{2}^{t}\right)+\left(c I+C^{\prime}\right)\left(b I+B_{2}^{t}\right) \\
= & a\left(M-M_{2}^{t}\right)+M A_{2}^{t}-A^{\prime} M_{2}^{t} \\
& +b\left(C^{\prime}-C_{2}^{\prime t}\right)+c\left(B_{2}^{t t}-B^{\prime}\right)-B^{\prime} C_{2}^{\prime t}+C^{\prime} B_{2}^{t} \\
= & 0 \tag{2.7}
\end{align*}
$$

Thus $M_{2}=M^{t}, B_{2}^{\prime}=B^{\prime t}$, and $C_{2}^{\prime}=C^{\prime t}$. As $B_{2}=\left(b I+B_{2}^{\prime}\right)$ and $C_{2}=\left(c I-C_{2}^{\prime}\right)$ we have $B_{2}=B^{t}$ and $C_{2}=C^{t}$. By checking the orthogonality of block rows 1 and 3 we get $M_{3}=M^{t}$ and by checking block rows 2 and 3 we get $M^{t}=M_{3}=M_{2}^{t}=\left(M^{t}\right)^{t}=M$, so it follows that

$$
M=M^{t}
$$

By checking the orthogonality of the other block rows and columns we achieve a similar result for the other blocks so the matrix $P$ can be converted to the form

$$
P^{\prime}=\left[\begin{array}{cccc}
M & A & B & C  \tag{2.8}\\
A & -M & -C^{t} & B^{t} \\
-B & -C^{t} & M & A^{t} \\
C & -B^{t} & A^{t} & -M
\end{array}\right]
$$

By (2.7) we have $M A_{2}^{t}-A^{\prime} M_{2}^{t}=M A^{t}-A^{\prime} M^{t}=M A^{\prime t}-A^{\prime} M=0$, but we also know that $A^{\prime t}=-A^{\prime}$, so $M\left(A^{\prime t}-A^{\prime}\right)=-2 M A^{\prime}=0$ and thus

$$
\begin{equation*}
M A^{\prime}=0 . \tag{2.9}
\end{equation*}
$$

Now we want to find all the solutions of (2.9). As $n$ is odd and $A^{\prime}$ is a circulant matrix and $A^{t}=-A^{\prime}$, the row sum and column sum of each row and column of the matrix
$A^{\prime}$ is 0 and thus it is clear that $\pm \eta J$ is a solution of equation (2.9).
We will now show that $\pm \eta J$ is the only solution of (2.9). We know $M$ is a $\pm \eta$-matrix and $A^{\prime}$ is a $\{0, \pm \eta\}$-matrix. Let $A^{\prime}=\eta \mathcal{A}$ and $M=\eta \mathcal{M}$. So $\mathcal{M}$ is a $\pm 1$ and $\mathcal{A}$ is a $\{0, \pm 1\}$ matrix. By (2.9) we have $\mathcal{M A}=0 . \eta J$ is a solution of (2.9) so $J \mathcal{A}=0$. By adding these two equations we have $(\mathcal{M}+J) \mathcal{A}=0$. Let $\mathcal{N}=(\mathcal{M}+J) / 2$. Then $\mathcal{N}$ is a $\{0,1\}$ matrix and

$$
\begin{equation*}
\mathcal{N A}=0 \tag{2.10}
\end{equation*}
$$

If $\mathcal{N}$ is a solution of (2.10) in $\mathbb{Z}$ it should be a solution of (2.10) in $\mathbb{Z}_{2}$. In $\mathbb{Z}_{2}, \mathcal{A}=$ $\operatorname{circ}(0,1, \ldots, 1)=J-I . \operatorname{In} \mathbb{Z}_{2}$ by (2.10) we have

$$
\mathcal{N A}=\mathcal{N}(J-I)=0
$$

so

$$
\mathcal{N}=\mathcal{N} J .
$$

As $\mathcal{N}$ is a circulant matrix it has constant row sum and column sum. It is clear that $\mathcal{N} J$ is either 0 or $J$. So, $\mathcal{N}$ is either 0 or $J$.

Thus $\pm J$ is the only solution for $\mathcal{M}$ and $\pm \eta J$ is the only solution for $M$. As $M= \pm \eta J$ by (2.6) we have

$$
\begin{equation*}
\eta^{2} J^{2}-A^{\prime 2}-B^{\prime 2}-C^{\prime 2}=(4 n-3) \eta^{2} I \tag{2.11}
\end{equation*}
$$

Let $e_{n}$ be an $n \times 1$ vector of all ones. Since the row sums and column sums of the matrices $A^{\prime}, B^{\prime}$, and $C^{\prime}$ are zero we have $e_{n} A^{\prime}=e_{n} B^{\prime}=e_{n} C^{\prime}=0$. By multiplying the two sides of equation (2.11) by $e_{n}$ we have

$$
\eta^{2} n^{2} e_{n}=\eta^{2}(4 n-3) e_{n}
$$

Thus $(n-3)(n-1)=0$ and $n=1$ or 3 , and this completes the proof.

### 2.2 An exhaustive search

We were able to prove using an exhaustive search that the only orthogonal design of order 12 constructible from 16 circulant blocks on 4 variables is $O D(12 ; 1,1,1,9)$. The main technique in this exhaustive search is the reversing process which was introduced
for the first time in [11]. In order to find the desired orthogonal designs, first we characterise all Hadamard matrices of order 12 constructible from 16 circulant blocks. We start by finding all $3 \times 12,\{ \pm 1\}$ matrices

$$
H^{\prime \prime}=\left[\begin{array}{llll}
H_{11} & H_{12} & H_{13} & H_{14}
\end{array}\right]
$$

constructible from four circulant blocks $H_{11}, H_{12}, H_{13}$, and $H_{14}$ such that:

$$
H^{\prime \prime} H^{\prime \prime t}=12 I_{3}
$$

Let $\mathcal{H}^{\prime \prime}$ be the set of matrices $H^{\prime \prime}$ that we have found. Now by checking all the pairs $H_{1}^{\prime \prime}, H_{2}^{\prime \prime} \in \mathcal{H}^{\prime \prime}$ such that

$$
H_{1}^{\prime \prime} H_{2}^{\prime \prime t}=0
$$

we are able to find all $6 \times 12,\{ \pm 1\}$ matrices

$$
H^{\prime}=\left[\begin{array}{llll}
H_{11} & H_{12} & H_{13} & H_{14} \\
H_{21} & H_{22} & H_{23} & H_{24}
\end{array}\right]
$$

constructible from 8 circulant blocks $H_{i j}, i=1,2$ and $j=1,2,3,4$ such that

$$
H^{\prime} H^{\prime t}=12 I_{6} .
$$

Continuing the same method by checking all the pairs of above matrices that satisfy the orthogonality condition we can find all Hadamard matrices $H=\left[H_{i j}\right], 1 \leq i, j \leq 4$ constructible from 16 circulant blocks. Now we implement the reversing process. Consider that $H_{1}=\left[h_{i j}\right]$ and $H_{2}=\left[k_{i j}\right]$ are two Hadamard matrices of order 12 constructible from 16 circulant blocks. Let $D=\left[d_{i j}\right]$ such that:

$$
d_{i j}=\left\{\begin{array}{l} 
\pm a \text { if } h_{i j}= \pm 1 \text { and } k_{i j}= \pm 1 \\
\pm b \text { if } h_{i j}= \pm 1 \text { and } k_{i j}=\mp 1
\end{array}\right.
$$

Then $D$ is a candidate for an orthogonal design of order 12 constructible from 16 circulant blocks on 2 variables $a$ and $b$. If $D$ is orthogonal we are done. Comparing all possible pairs of matrices $H_{1}$ and $H_{2}$ we classify all desired orthogonal designs on 2 variables. All we found were one of each of $O D(12 ; 9,3), O D(12 ; 10,2)$, and $O D(12 ; 11,1)$. From this fact it is clear that $O D(12 ; 1,1,1,9)$ is the only orthogonal
design of order 12 constructible from 16 circulant blocks. We tried to use the same method to classify orthogonal designs of order 20 constructible from 16 circulant blocks. Because in the first stage the number of $5 \times 20$ matrices $H^{\prime \prime}$ constructible from 4 circulant blocks such that $H^{\prime \prime} H^{\prime \prime t}=20 I_{5}$ is huge, we were not able to run the second stage. However we did a random search instead of an exhaustive search and found an $O D(20 ; a, b)$ constructible from 16 circulant blocks for each pair ( $a, b$ ), such that $1 \leq a, b \leq 19$ and $a+b=20$.

### 2.3 A non-existence theorem

In this section we show that there do not exist amicable $T$-matrices of odd order.
Theorem 2.9 There are no four full circulant $T$-matrices $T_{1}, T_{2}, T_{3}$, and $T_{4}$ of order $n$ if $n$ is odd satisfying:

$$
\begin{equation*}
T_{1} T_{2}^{t}-T_{2} T_{1}^{t}+T_{3} T_{4}^{t}-T_{4} T_{3}^{t}=0 \tag{2.12}
\end{equation*}
$$

Proof Assume otherwise for a contradiction. Reduce the matrices mod 2, (notice that $A \equiv-A$ for every matrix $A$.) Let $U=T_{1}+T_{2}$ and $V=T_{3}+T_{4}$. Then using the complementary and amicability conditions we obtain:

$$
U U^{t}+V V^{t}=\left(\sum_{i} T_{i} T_{i}^{t}\right)+T_{1} T_{2}^{t}+T_{2} T_{1}^{t}+T_{3} T_{4}^{t}+T_{4} T_{3}^{t}=I .
$$

We have $U+V=J$, so $V=U+J$. Using that $T_{i} J^{t}=J T_{i}^{t}$ for circulant matrices $T_{i}$ we have

$$
\begin{aligned}
I & \equiv U U^{t}+V V^{t} \\
& \equiv U U^{t}+U U^{t}+U J^{t}+J U^{t}+J J^{t} \\
& \equiv J J^{t} \\
& \equiv J .
\end{aligned}
$$

This is a contradiction.

### 2.4 A family of $T$-matrices

In this section we introduce an infinite family of $T$-matrices. These matrices were introduced by Xia and Xia in [17]. The method is to divide $G F\left(q^{2}\right)$ where $q=8 m+3$ is a prime power into so called $C$-partitions. Note that we are reproducing the work of Xia and Xia in [17] and [16] here in this thesis with some minor modifications.

In order to construct such matrices we show that a special class of supplementary difference sets exists. Supplementary difference set (SDS) is a generalisation of difference set. Let $G$ be an abelian group with addition $\oplus$, subtraction $\Theta$, and zero element $\theta$. Consider the group ring $\mathbb{Z}[G]$ of the group $G$ over the ring of integers; the elements of $Z[G]$ can be expressed as polynomials

$$
\sum_{i} a_{i} g_{i}
$$

where $a_{i} \in \mathbb{Z}$ and $g_{i} \in G$. In $\mathbb{Z}[G]$ addition is defined by:

$$
\left(\sum_{i} a_{i} g_{i}\right)+\left(\sum_{i} b_{i} g_{i}\right)=\sum_{i}\left(a_{i}+b_{i}\right) g_{i}
$$

If $G$ is a finite field multiplication is defined by:

$$
\left(\sum_{i} a_{i} g_{i}\right)\left(\sum_{i} b_{i} g_{i}\right)=\sum_{k}\left(\sum_{g_{i} g_{j}=g_{k}} a_{i} b_{j}\right) g_{k} .
$$

Let

$$
T=\sum_{g \in G} g \text { and } T^{*}=T-\theta
$$

For non-empty subsets $A$ and $B$ of $G$ we define:

$$
\begin{gathered}
A \ominus B=\sum_{a \in A, b \in B}(a \ominus b), \\
\Delta A=A \ominus A, \\
\Delta(A, B)=(A \ominus B)+(B \in A) ; \\
\Delta \emptyset=\Delta(\emptyset: A)=0 .
\end{gathered}
$$

It is easy to see that $\Delta(A, A)=2 \Delta(A)$.
The following trivial identitics are useful:
If $B \cap C=\emptyset$ then

$$
\begin{gather*}
\Delta(A, B \cup C)=\Delta(A, B)+\Delta(A, C)  \tag{2.13}\\
\Delta(B \cup C)=\Delta(B)+\Delta(B, C)+\Delta(C) \tag{2.14}
\end{gather*}
$$

Definition 2.10 $A k$-subset $D$ of an abelian group $G$ of order $v$ is called a $(v, k, \lambda)$ difference set if

$$
\Delta D=(k-\lambda) \theta+\lambda T
$$

for some non-negative integer $\lambda$.
Definition 2.11 A collection of subsets $\left\{D_{1}, D_{2}, \ldots, D_{r}\right\}$ of an abelian group $G$ of order $v$ such that $\left|D_{i}\right|=k_{i}$ is called a $\left(v, k_{1}, k_{2}, \ldots, k_{r}, \lambda\right)$-supplementary difference set if

$$
\Delta D=\left(\sum_{i=1}^{r} k_{i}-\lambda\right) \theta+\lambda T
$$

for some non-negative integer $\lambda$.
Clearly if $r=1$ the supplementary difference set is equivalent to a difference set.
If $r=4$ and $\lambda=\sum_{i=1}^{4} k_{i}-v$ the collection $\left\{D_{1}, D_{2}, D_{3}, D_{4}\right\}$ is called an $\operatorname{SDS}$ of type H. Now we show that an SDS of type H exists where $G=G F\left(q^{2}\right), q \equiv 3(\bmod 8)$ is a prime power, and every element of $G$ appears an even number of times in the system of $\left\{D_{1}, D_{2}, D_{3}, D_{4}\right\}$. Later we prove that one can construct $T$-matrices using this particular type of SDS.

Consider that $v=q^{2}, q=4 m+3$ is a prime power, and $g$ is a generator of the multiplicative group of $G=G F(v)$. Define

$$
\begin{aligned}
& E_{i}:=\left\{g^{8(m+1) j+i} \mid j=0, \ldots, 2 m\right\}, i=0,1, \ldots, 8 m+7, \\
& S_{i}:=E_{i} \cup E_{i+4 m+4}, T_{i}:=\sum_{h \in S_{i}} h, i=0,1, \ldots, 4 m+3 .
\end{aligned}
$$

We have:

$$
\begin{aligned}
\sum_{i=0}^{4 m+3} T_{i} & =\sum_{i=0}^{4 m+3} \sum_{h \in S_{i}} h \\
& =\sum_{i=0}^{4 m+3} \sum_{j=0}^{2 m}\left(g^{4(m+1)(2 j)+i}+g^{4(m-1)(2 j+1)+i}\right) \\
& =16 m^{2}+24 m+8 \\
& =\sum_{k=0}^{q^{2}-1} g^{k} \\
& =T^{*}
\end{aligned}
$$

Define

$$
E_{i}=E_{j} \text { as } i \equiv j(\bmod 8 \mathrm{~m}+8)
$$

$$
S_{i}=S_{j}, T_{i}=T_{j} \text { as } i \equiv j(\bmod 4 \mathrm{~m}+4)
$$

It is easy to see that $g E_{i}=E_{i+1}, g S_{i}=S_{i+1}$, and $g T_{i}=T_{i+1}$. Define

$$
\begin{gathered}
\Phi_{0}=\Delta E_{0} \\
\Phi_{i}=\Delta\left(E_{0}, E_{i}\right), i=1,2, \ldots, 8 m+7, \\
\Phi_{i}=\Phi_{j} \text { as } i \equiv j(\bmod 8 \mathrm{~m}+8)
\end{gathered}
$$

We have

$$
\begin{aligned}
\Delta E_{i} & =\sum_{j=0}^{2 m} \sum_{j^{\prime}=0}^{2 m} g^{8(m+1) j+i} \ominus g^{8(m+1) j^{\prime}+i} \\
& =\sum_{j=0}^{2 m} \sum_{j^{\prime}=0}^{2 m} g^{i}\left(g^{8(m+1) j} \ominus g^{8(m+1) j^{\prime}}\right) \\
& =g^{i} \sum_{j=0}^{2 m} \sum_{j^{\prime}=0}^{2 m} g^{8(m+1) j} \ominus g^{8(m+1) j^{\prime}} \\
& =g^{i} \Phi_{0}
\end{aligned}
$$

for $i=0,1, \ldots, 8 m+8$. Similarly we can show that

$$
\Delta\left(E_{i}, E_{j}\right)=g^{i} \Phi_{j-i}
$$

for $i \neq j$, and also

$$
\Phi_{i}=g^{i} \Phi_{-i}=g^{i} \Phi_{8 m+8-i}
$$

for $i=1,2, \ldots, 8 m+7$.
Lemma 2.12 Let $G=G F\left(q^{2}\right)$ be an extension of $G F(q)$ then

$$
E_{0} \cup E_{4 m+4}=G F(q)^{*} .
$$

Proof It is sufficient to show that $g^{4(m+1)} \in G F(q)$. Consider the polynomial $x^{q-1} \ominus$ $1=0$ in $G F\left(q^{2}\right)$. Clearly this polynomial has $q-1$ roots, since the order of the multiplicative group of $G F(q)$ is $q-1$ we have $x^{q-1}=1$ for all $x \in G F(q)$. Thus all the roots of the polynomial $x^{q-1} \ominus 1=0$ are in $G F(q)$. On the other hand we have

$$
\left(g^{4(m+1)}\right)^{q-1} \ominus 1=g^{q^{2}-1} \ominus 1=1 \ominus 1=0 .
$$

Since $g^{4(m+1)}$ is one of the roots of the polynomial $x^{g-1} \ominus 1=0$, it is in $G F(q)$. By a simple counting we have:

$$
E_{0} \cup E_{4 m+4}=G F(q)^{*} .
$$

Here we need to show that:
Lemma 2.13 [1] The set of all non-zero squares in $G F(q)$ form a $\left(q, \frac{1}{2}(q-1), \frac{1}{4}(q-3)\right)-$ difference set.

Proof Let $\alpha$ be a primitive element of $G F(q)$ and let $D$ be the set of all non-zero squares in $G F(q)$. We have $D=\left\{\alpha^{0}, \alpha^{2}, \ldots, \alpha^{4 m}\right\}$. Since $q \equiv 3(\bmod 4)$ we have $-1 \notin D$ and $-D=\left\{\alpha, \alpha^{3}, \ldots, \alpha^{4 m+1}\right\}$. Let $a_{i}$ and $b_{i}, i=1, \ldots n$ be the set of all integers such that

$$
1=\alpha^{2 a_{i}} \ominus \alpha^{2 b_{i}}
$$

Then for any $\alpha^{2 t} \in D$ we have

$$
\alpha^{2 t}=\alpha^{2\left(a_{i}+t\right)} \ominus \alpha^{2\left(b_{i}+t\right)} .
$$

So every representation of 1 as the difference of the elements of $D$ gives us a representation of $\alpha^{2 t}$ as the difference of the elements of $D$ and vice versa. For any element $\alpha^{2 t+1} \notin D$ we have $\alpha^{2 t+1} \in-D$ so $\alpha^{2 t+1}=-\alpha^{2 t^{\prime}}$ for some integer $t^{\prime}$. we have

$$
\alpha^{2 t+1}=\alpha^{2\left(b_{i}+t^{\prime}\right)} \ominus \alpha^{2\left(2_{i}+t^{\prime}\right)}
$$

Thus every representation of 1 as the difference of the elements of $D$ gives us a representation of $\alpha^{2 t+1}$ as the difference of the elements of $D$ and vice versa. So $D$ is a difference set in $G F(q)$. Clearly $k=|D|=\frac{1}{2}(q-1)$. Since we have $k(k-1)$ differences in $D$ and each of the $q-1$ non-zero elements of $G F(q)$ appears $\lambda$ times we have $k(k-1)=\lambda(q-1)$ so we have $\lambda=\frac{1}{4}(q-3)$.

Lemma 2.14 The polynomials $\Phi_{i}$ satisfy the following properties:
(i) $\Phi_{0}=(2 m+1) \theta+m T_{0}$;
(ii) $\Phi_{4 m+4}=(2 m+1) T_{0}$;
(iii) $\Phi_{i}-\Phi_{i+4 m+4}=T^{*}-T_{0}-T_{i}, i=1,2, \ldots, 4 m+3$.

Proof To prove (i) using Lemma 2.12 and 2.13 we get

$$
\Phi_{0}=\Delta E_{0}=\left|E_{0}\right| \theta+m T_{0}=(2 m+1) \theta+m T_{0}
$$

To prove (ii) we have:

$$
\begin{aligned}
\Phi_{4 m+4} & =\Delta\left(E_{0}, E_{4 m+4}\right) \\
& =\Delta\left(E_{0}, G F(q) \backslash\left(E_{0} \cup \theta\right)\right) \\
& =\Delta\left(E_{0}, G F(q)\right)-\Delta\left(E_{0}, E_{0}\right)-\Delta\left(E_{0}, \theta\right) \\
& =2\left|E_{0}\right|\left(T_{0}+\theta\right)-2 \Delta\left(E_{0}\right)-T_{0} \\
& =2(2 m+1) T_{0}+2(2 m \div 1) \theta-2(2 m+1) \theta-2 m T_{0}-T_{0} \\
& =(2 m+1) T_{0} .
\end{aligned}
$$

Since $q \equiv 3(\bmod 4)$ the polynomial $x^{2} \oplus 1$ is irreducible in $G F(q)$ and the elements of $G F\left(q^{2}\right)$ can be represented by polynomials $a i \ominus b, a ; b \in G F(q)$ where $i^{2}=-1$. Let
$h=g^{4(m-1)}$, we know that $h$ is a primitive element of $G F(q)$. We have $\left(g^{2(m+1)}\right)^{2}=$ $h^{1}=-h^{2 t}=i^{2} h^{2 t}$ for some integer $t$, so

$$
g^{2 m+2}=h^{t} i
$$

Thus we have:

$$
\begin{aligned}
E_{0} & =\left\{h^{2 j} \mid j=0, \ldots, 2 m\right\}, \\
S_{2 m+2} & =\left\{h^{j} i \mid j=0, \ldots, 4 m-1\right\} .
\end{aligned}
$$

Now we have:

$$
\begin{aligned}
\Phi_{2 m+2}+\Phi_{\mathrm{G} m+6} & =\Delta\left(E_{0}, E_{2 m+2}\right)+\Delta\left(E_{0}, E_{6 m+6}\right) \\
& =\Delta\left(E_{0}, S_{2 m+2}\right) \\
& =\sum_{\substack{0 \leq \leq \leq 4 m+1 \\
0 \leq k \leq 2 m}}\left(\left(h^{2 k} \ominus h^{j} i\right)+\left(h^{j} i \ominus h^{2 k}\right)\right) \\
& =\sum_{\substack{0 \leq \leq \leq 4 m+1 \\
0 \leq k \leq 2 m}}\left(\left(h^{2 k} \oplus h^{j} i\right)+\left(h^{j} i \oplus h^{2 k+1}\right)\right) \\
& =\sum_{0 \leq j, k \leq 1 m+1}^{0}\left(h^{j} i \oplus h^{k}\right) \\
& =T^{*}-T_{0}-T_{2 m+2}
\end{aligned}
$$

For $1 \leq l \leq 4 m+3$ and $l \neq 2 m+2$ we have $g^{l}=h^{\alpha} i \oplus h^{\beta}$ for some integers $\alpha$ and $\beta$. We have:

$$
S_{l}=E_{l} \cup E_{l+4 m+4}=\left\{h^{\alpha+j} i \oplus h^{\beta+j} \mid j=0, \ldots 4 m-1\right\} .
$$

Thus

$$
\begin{aligned}
\Phi_{l}+\Phi_{l+4 m+4} & =\Delta\left(E_{0}, S_{l}\right) \\
& =\sum_{\substack{0 \leq j \leq 4 m+1 \\
0 \leq k \leq 2 m}}\left(\left(h^{2 k} \ominus\left(h^{\alpha+j} i \oplus h^{\beta+j}\right)\right)+\left(\left(h^{\alpha+j} i \oplus h^{\beta+j}\right) \ominus h^{2 k}\right)\right) \\
& =\sum_{\substack{0 \leq \leq \leq 4 m+1 \\
0 \leq k \leq 2 m}}\left(\left(h^{2 k} \ominus h^{\alpha+j} i \oplus h^{\beta+j}\right)+\left(h^{\alpha+j} i \ominus h^{\beta+j} \oplus h^{2 k-1}\right)\right) \\
& =\sum_{0 \leq j, k \leq 4 m+1}\left(h^{\alpha+j} i \ominus\left(h^{\beta+j} \oplus h^{k}\right)\right) \\
& =\sum_{\substack{0 \leq 4 \leq 4+1 \\
0 \leq G \in G F(q)}}\left(h^{\alpha+j} i \oplus a\right)-\sum_{0 \leq j \leq 4 m+1}\left(h^{\alpha+j} i \oplus h^{\beta+j}\right) \\
& =T^{*}-T_{0}-T_{i} .
\end{aligned}
$$

Lemma 2.15 If $D=\cup_{i=0}^{2 t} E_{a_{i}} \cup\left(\cup_{j=1}^{2 m+1-t} S_{b_{j}}\right), 0 \leq t \leq 2 m+1$, where $a_{i} \not \equiv a_{j}(\bmod 4 \mathrm{~m}+$ 4) for $i \neq j(\bmod 4 \mathrm{~m}+4)$, and $a_{i} \not \equiv b_{j}, i=0, \ldots, 2 t, j=1, \ldots, 2 m+1-t$, then

$$
\begin{aligned}
\Delta D= & 2(2 m+1)(2 m+1-t) \theta+\left(4 m^{2}+4 m+1-t^{2}\right) T^{*} \\
& +(t-2 m-1) \sum_{i=0}^{2 t} T_{a_{i}}+\Delta\left(\cup_{i=0}^{2 t} E_{a_{i}}\right)
\end{aligned}
$$

Proof We have:

$$
\begin{aligned}
\Delta\left(E_{a_{i}}, S_{b_{j}}\right) & =\Delta\left(E_{a_{i}}, E_{b_{j}}\right)-\Delta\left(E_{a_{i}}: E_{b_{j}+4 m+4}\right) \\
& =g^{a_{i}} \Phi_{b_{j}-a_{i}}+g^{a_{i}} \Phi_{b_{j}-a_{i}+4 m+4} \\
& =g^{a_{i}}\left(\Phi_{b_{j}-a_{i}}+\Phi_{b_{j}-a_{i}+4 m n+4}\right) \\
& =g^{a_{i}}\left(T^{*}-T_{0}-T_{b_{j}-a_{i}}\right) \\
& =T^{*}-T_{a_{i}}-T_{b_{j}} .
\end{aligned}
$$

Thus

$$
\begin{aligned}
\Delta\left(\cup_{i=0}^{2 t} E_{a_{i}}, \cup_{j=1}^{2 m+1-t} S_{b_{j}}\right)= & \sum_{i=0}^{2 t} \sum_{j=1}^{2 m+1-t} \Delta\left(E_{a_{i}}, S_{b_{j}}\right) \\
= & \sum_{i=0}^{2 t} \sum_{j=1}^{2 m+1-t}\left(T^{*}-T_{a_{i}}-T_{b_{j}}\right) \\
= & (2 t+1)(2 m+1-t) T^{*}-(2 t+1) \sum_{j=1}^{2 m+1-t} T_{b_{j}} \\
& -(2 m+1-t) \sum_{i=0}^{2 t} T_{a_{i}} .
\end{aligned}
$$

We have:

$$
\begin{aligned}
\Delta\left(S_{b_{j}}\right) & =\Delta\left(E_{b_{j}}\right)+\Delta\left(E_{b_{j}+4 m+4}\right)+\Delta\left(E_{b_{j}}, E_{b_{j}+4 m+4}\right) \\
& =g^{b_{j}} \Phi_{0}+g^{b_{j}+4 m+4} \Phi_{0}+g^{b_{j}} \Phi_{4 m+4} \\
& \left.=g^{b_{j}}(2 m+1) \theta+m T_{0}\right]+g^{b_{j}} g^{4 m+4}\left[(2 m+1) \theta+m T_{0}\right]+g^{b_{j}}(2 m+1) T_{0} \\
& =(2 m+2) \theta+(4 m+1) T_{b_{j}} .
\end{aligned}
$$

If $i \neq j$ we have

$$
\begin{aligned}
\Delta\left(S_{b_{i}}, S_{b_{j}}\right)= & \Delta\left(E_{b_{i}}, E_{b_{j}}\right)+\Delta\left(E_{b_{i}}, E_{b_{j}+4 m+4}\right)+\Delta\left(E_{b_{i}+4 m+4}, E_{b_{j}}\right) \\
& +\Delta\left(E_{b_{i}+4 m+4}, E_{b_{j}+4 m+4}\right) \\
= & g^{b_{i}}\left(\Phi_{b_{j}-b_{i}}+\Phi_{b_{j}-b_{i}+4 m+4}\right)+g^{b_{i}+4 m+4}\left(\Phi_{b_{j}-b_{i}}+\Phi_{b_{j}-b_{i}+4 m+4}\right) \\
= & g^{b_{i}}\left(T^{*}-T_{0}-T_{b_{j}-b_{i}}\right)+g^{b_{i}} g^{4 m+4}\left(T^{*}-T_{0}-T_{b_{j}-b_{i}}\right) \\
= & 2 g^{b_{i}}\left(T^{*}-T_{0}-T_{b_{j}-b_{i}}\right) \\
= & 2\left(T^{*}-T_{b_{i}}-T_{b_{j}}\right) .
\end{aligned}
$$

Thus

$$
\begin{aligned}
\Delta\left(\cup_{j=1}^{2 m+1-t} S_{b_{j}}\right)= & \sum_{j=1}^{2 m+1-t} \Delta S_{b_{j}}+\sum_{i=1}^{2 m-t} \sum_{j=i+1}^{2 m+1-t} \Delta\left(S_{b_{i}}, S_{b_{j}}\right) \\
= & (2 m+1-t)(4 m+2) \theta+(4 m+1) \sum_{j=1}^{2 m+1-t} T_{b_{j}} \\
& +\sum_{i=1}^{2 m-t 2 m+1-t} \sum_{j=i+1} 2\left(T^{*}-T_{b_{i}}-T_{b_{j}}\right) \\
= & (2 m+1-t)(4 m+2) \theta+(2 t+1) \sum_{j=1}^{2 m+1-t} T_{b_{j}} \\
& +(2 m-t)(2 m+1-t) T^{*}
\end{aligned}
$$

Now we have:

$$
\begin{aligned}
\Delta D= & \Delta\left(\cup_{i=0}^{2 t} E_{a_{i}}\right)+\Delta\left(\cup_{j=1}^{2 m+1-t} S_{b_{j}}\right)+\Delta\left(\cup_{i=0}^{2 t} E_{a_{i}}, \cup_{j=1}^{2 m+1-t} S_{b_{j}}\right) \\
= & 2(2 m+1)(2 m+1-t) \theta+\left(4 m^{2}+4 m+1-t^{2}\right) T^{*} \\
& +(t-2 m-1) \sum_{i=0}^{2 t} T_{a_{i}}+\Delta\left(\cup_{i=0}^{2 t} E_{a_{i}}\right) .
\end{aligned}
$$

Let $m=2 r$. We have $q=8 r-3$ is a prime power. Define:

$$
\begin{aligned}
F_{i} & :=\cup_{j=0}^{2 r} E_{8 j+i}, \quad i=0,1, \ldots, 7 \\
G_{i} & :=\sum_{a \in F_{i} \cup F_{i+4}} a, \quad i=0,1,2,3
\end{aligned}
$$

Lemma 2.16 The subsets $F_{i}, i=0, \ldots, 7$, have the following properties:
(i) $\Delta\left(F_{0}, F_{5}\right)=\Delta\left(F_{1}, F_{4}\right)$;
(ii) $2\left(\sum_{i=0}^{3} g^{i}\right) \Delta F_{0}=8(2 r+1)(4 r+1) \theta+((2 r+1)(4 r+1)-1) T^{*}$;
(iii) $\left(\sum_{i=0}^{3} g^{i}\right) \Delta\left(F_{0}, F_{3}\right)=(2 r+1)(4 r \div 1) T^{*}$;
(iv) $\Delta\left(F_{0}, F_{2} \cup F_{6}\right)=(2 r+1)^{2} T^{*}-(2 r+1)\left(G_{0}+G_{2}\right)$.

Proof To prove (i) first we have to show that

$$
h \Phi_{i}=\Phi_{i}
$$

where $h=g^{4 m \dot{ } 4}$. We have:

$$
\begin{aligned}
h \Phi_{i} & =h \Delta\left(E_{0}, E_{i}\right)=\Delta\left(h E_{0}, h E_{i}\right) \\
& =\Delta\left(\ominus E_{0}, \ominus E_{i}\right)=\Delta\left(E_{0}, E_{i}\right) \\
& =\Phi_{i} .
\end{aligned}
$$

Now we have:

$$
\begin{aligned}
\Delta\left(F_{1}, F_{4}\right) & =\sum_{i=0}^{2 r} \sum_{j=0}^{2 r} \Delta\left(E_{8 i+1}, E_{8 j+4}\right) \\
& =\sum_{i=0}^{2 r} \sum_{j=0}^{2 r} \Delta\left(E_{8(i-r)+1}, E_{8(j+r)+4}\right) \\
& =\sum_{i=0}^{2 r} \sum_{j=0}^{2 r} g^{8 j+8 r+4} \Phi_{8(j-i+2 r)+3} \\
& =\sum_{i=0}^{2 r} \sum_{j=0}^{2 r} g^{8 j+4 m+4} \Phi_{8 m+8-8(j-i+m)-3} \\
& =\sum_{i=0}^{2 r} \sum_{j=0}^{2 r} g^{8 j} g^{4 m+4} \Phi_{8(i-j)+5} \\
& =\sum_{i=0}^{2 r} \sum_{j=0}^{2 r} g^{8 j} \Phi_{8(i-j)+\bar{j}} \\
& =\sum_{i=0}^{2 r} \sum_{j=0}^{2 r} \Delta\left(E_{8 j}, E_{8 i+5}\right) \\
& =\Delta\left(F_{0}, F_{5}\right) .
\end{aligned}
$$

To prove (ii) we follow the proof of Lemma 2.13. Let $a_{i}$ and $b_{i}, i=1, \ldots n$ be the set of all integers such that

$$
g^{l}=g^{8 a_{i}} \ominus g^{8 b_{i}}, l=0,1,2,3
$$

Then for any $g^{8 t+i}$ we have

$$
g^{8 t+l}=g^{8\left(a_{i}+t\right)} \ominus g^{8\left(b_{i}+t\right)}
$$

So every representation of $g^{l}$ as the difference of the elements of $F_{0}$ gives us a representation of $g^{8 t-l}$ as the difference of the elements of $F_{0}$ and vice versa. For any element $g^{8 t+l+4}$ we have $g^{8 t+l+4}=\Theta g^{8 t^{\prime}+l}$ for some integer $t^{\prime}$, thus

$$
g^{8 t+l+4}=g^{8\left(b_{i}+t^{\prime}\right)} \ominus g^{8\left(a_{i}+t^{\prime}\right)}
$$

So every representation of $g^{l}$ as the difference of the elements of $F_{0}$ gives us a representation of $g^{8 t+l+4}$ as the difference of the elements of $F_{0}$ and vice versa. So we have:

$$
\Delta F_{0}=(2 r+1)(4 r+1) \theta+\sum_{i=0}^{3} \alpha_{i} G_{i} .
$$

Now by counting the number of terms of the two sides of the above equation we have:

$$
(2 r+1)^{2}(4 r+1)^{2}=(2 r+1)(4 r+1)+2(2 r+1)(4 r+1) \sum_{i=0}^{3} \alpha_{i}
$$

SO

$$
\sum_{i=0}^{3} \alpha_{i}=\frac{1}{2}[(2 r+1)(4 r+1)-1]
$$

Thus we have:

$$
2\left(\sum_{i=0}^{3} g^{i}\right) \Delta F_{0}=8(2 r+1)(4 r+1) \theta+((2 r+1)(4 r+1)-1) T^{*}
$$

To prove (iii), using the same argument one can say that:

$$
\Delta\left(F_{0}, F_{3}\right)=\sum_{i=0}^{3} \alpha_{i} G_{i} .
$$

Counting the number of terms of the two sides of the above equation we have:

$$
2(2 r+1)^{2}(4 r+1)^{2}=2(2 r+1)(4 r+1) \sum_{i=0}^{3} \alpha_{i} .
$$

Thus

$$
\sum_{i=0}^{3} \alpha_{i}=(2 r+1)(4 r+1)
$$

Now we have:

$$
\left(\sum_{i=0}^{3} g^{i}\right) \Delta\left(F_{0}, F_{3}\right)=(2 r+1)(4 r+1) T^{*}
$$

To prove (iv) we have:

$$
\begin{aligned}
\Delta\left(F_{0}, F_{2} \cup F_{6}\right) & =\sum_{i=0}^{2 r} \sum_{j=0}^{2 r} \Delta\left(E_{8 i:} E_{8 j+2} \cup E_{8(j+r)+6}\right) \\
& =\sum_{i=0}^{2 r} \sum_{j=0}^{2 r} g^{8 i}\left(\Phi_{8(j-i)+2}+\Phi_{8(j-i)+8 r+6}\right) \\
& =\sum_{i=0}^{2 r} g^{8 i} \sum_{j=0}^{2 r}\left(T^{*}-T_{0}-T_{8(j-i)+2}\right) \\
& =(2 r+1)^{2} T^{*}-(2 r+1) \sum_{i=0}^{2 r}\left(T_{8 i}+T_{8 i+2}\right) \\
& =(2 r+1)^{2} T^{*}-(2 r+1)\left(G_{0}+G_{2}\right) .
\end{aligned}
$$

Theorem 2.17 There is an $S D S\left\{D_{1}, D_{2}, D_{3}, D_{4}\right\}$ of type $H$ in $G F(q)$ such that every element of $G F(q)$ appears an even number of times in the system of $\left\{D_{1}, D_{2}, D_{3}, D_{4}\right\}$, where $q=8 r+3$ is a prime power.

Proof Let

$$
\begin{gathered}
D_{1}=\left(\cup_{i=0}^{r-1} S_{8 i+1}\right) \cup F_{0} \cup F_{3} \cup F_{6}, \\
D_{2}=\left(\cup_{i=0}^{r-1} S_{8 i}\right) \cup\left(\cup_{i=r}^{2 r} S_{8 i+2}\right) \cup\left(\cup_{i=0}^{r-1} S_{8 i+3}\right) \cup F_{1}, \\
D_{3}=\left(\cup_{i=0}^{r-1} S_{8 i+3}\right) \cup F_{0} \cup F_{2} \cup F_{5} ; \\
D_{4}=\left(\cup_{i=0}^{r-1} S_{8 i}\right) \cup\left(\cup_{i=r}^{2 r} S_{8 i+1}\right) \cup\left(\cup_{i=0}^{r-1} S_{8 i+2}\right) \cup F_{3} .
\end{gathered}
$$

It is easy to see that each of the subsets $D_{1}, D_{2}, D_{3}$, and $D_{4}$ satisfies the conditions of Lemma 2.15, so we have:

$$
\begin{aligned}
& \Delta D_{1}=2 r(4 r+1) \theta+\left(7 r^{2}+2 r\right) T^{*}-r\left(G_{0}+G_{2}+G_{3}\right)+\Delta\left(F_{0} \cup F_{3} \cup F_{6}\right), \\
& \Delta D_{2}=2(4 r+1)(3 r+1) \theta+\left[(4 r+1)^{2}-r^{2}\right] T^{*}-(3 r+1) G_{1}+\Delta F_{1}, \\
& \Delta D_{3}=2 r(4 r+1) \theta+\left(7 r^{2}+2 r\right) T^{*}-r\left(G_{0}+G_{1}+G_{2}\right)+\Delta\left(F_{0} \cup F_{2} \cup F_{5}\right), \\
& \Delta D_{4}=2(4 r-1)(3 r+1) \theta+\left[(4 r+1)^{2}-r^{2}\right] T^{*}-(3 r+1) G_{3}+\Delta F_{3} .
\end{aligned}
$$

Following the proof of Lemma 2.16 part (iii) one can easily show that $\Delta F_{1}=\Delta F_{5}$ and $\Delta F_{2}=\Delta F_{6}$. Now we have

$$
\begin{aligned}
\sum_{i=1}^{4} \Delta D_{i}= & 4(4 r+1)^{2} \theta+2\left(22 r^{2}-10 r+1\right) T^{*}-2 r\left(G_{0}+G_{1}+G_{2}+G_{3}\right) \\
& -(2 r+1)\left(G_{1}+G_{3}\right)+2 \Delta F_{0}+2 \Delta F_{3}+\Delta F_{1}+\Delta F_{2}+\Delta F_{5}+\Delta F_{6} \\
& +\Delta\left(F_{0}, F_{3}\right)+\Delta\left(F_{0}, F_{5}\right)+\Delta\left(F_{2}, F_{5}\right)+\Delta\left(F_{3}, F_{6}\right)+\Delta\left(F_{0}, F_{2}\right)-\Delta\left(F_{0}, F_{6}\right) \\
= & 4(4 r+1)^{2} \theta+2\left(22 r^{2}+9 r+1\right) T^{*}-(2 r+1)\left(G_{1}+G_{3}\right) \\
& +2\left(\Delta F_{0}+\Delta F_{1}+\Delta F_{2}+\Delta F_{3}\right)+\Delta\left(F_{0}, F_{3}\right)+\Delta\left(F_{1}, F_{4}\right)+\Delta\left(F_{2}, F_{5}\right) \\
& +\Delta\left(F_{3}, F_{6}\right)+\Delta\left(F_{0}, F_{2} \cup F_{6}\right) \\
= & 4(4 r+1)^{2} \theta+2\left(22 r^{2}+9 r+1\right) T^{*}-(2 r+1)\left(G_{1}+G_{3}\right) \\
& +2\left(\sum_{i=0}^{3} g^{i}\right) \Delta F_{0}+\left(\sum_{i=0}^{3} g^{i}\right) \Delta\left(F_{0}, F_{3}\right)+\Delta\left(F_{2}, F_{5}\right) \\
= & 4(8 r+3)(4 r+1) \theta+\left(64 r^{2}+32 r+3\right) T^{*} \\
= & q^{2} \theta+q(q-2) T .
\end{aligned}
$$

It is easy to check that every element of $G$ appears an even number of times in the system of $\left\{D_{1}, D_{2}, D_{3}, D_{4}\right\}$ and the proof is complete.

Next we want to show the relationship between SDSs and $T$-matrices. In order to make the connection we should introduce the concept of a $C$-partition of an abelian group. We construct $T$-matrices from $C$-partitions and $C$-partitions from supplementary difference sets of type H such that every element of the abelian group appears an even number of times in the system of our SDS.

Definition 2.18 The family of subsets $\left(A_{1}, A_{2}, \ldots, A_{8}\right)$ of an abelian group $G$ of order $v$ is called a $C$-partition if it satisfies the following conditions:
(i) $A_{i} \cap A_{j}=\emptyset$;
(ii) $\cup_{i=1}^{\ell} A_{i}=G$;
(iii) $\sum_{i=1}^{8} \Delta A_{i}=v \theta+\sum_{i=1}^{4} \Delta\left(A_{i}, A_{i+4}\right)$.

Theorem 2.19 There is a $C$-partition $\left(A_{1}, A_{2}, \ldots, A_{8}\right)$ of an abelian group $G$ of order $v$ if and only if there is an $\operatorname{SDS}\left\{D_{1}, D_{2}, D_{3}, D_{4}\right\}$ of type $H$ in $G$ such that every element of $G$ appears an even number of times in the system of $\left\{D_{1}, D_{2}, D_{3}, D_{4}\right\}$.

## Proof Let

$$
\begin{aligned}
& D_{1}=A_{1} \cup A_{2} \cup A_{3} \cup A_{4}, \\
& D_{2}=A_{1} \cup A_{2} \cup A_{7} \cup A_{8}, \\
& D_{3}=A_{1} \cup A_{6} \cup A_{3} \cup A_{8}, \\
& D_{4}=A_{1} \cup A_{6} \cup A_{7} \cup A_{4} .
\end{aligned}
$$

During this construction using 2.13, 2.14, and the fact that $G=\cup_{i=1}^{8} A_{i}$, it is not hard to show that:

$$
\begin{align*}
\sum_{i=1}^{4} \Delta D_{i} & =\Delta\left(A_{1}, G\right)-\Delta\left(A_{5}, G\right)+\sum_{i=1}^{8} A_{i}-\sum_{i=1}^{4} \Delta\left(A_{i}, A_{i+4}\right)+\Delta G \\
& =v \theta+\left(2\left(\left|A_{1}\right|-\left|A_{5}\right|\right)+v\right) T \\
& =v \theta+\left(\sum_{i=1}^{4}\left|D_{i}\right|-v\right) T \tag{2.15}
\end{align*}
$$

Thus $\left\{D_{1}, D_{2}, D_{3}, D_{4}\right\}$ is an SDS of type H ; it is clear that every element of $G$ appears an even number of times in the system of $\left\{D_{1}, D_{2}, D_{3}, D_{4}\right\}$.

Conversely, let $\left\{D_{1}, D_{2}, D_{3}, D_{4}\right\}$ be an SDS of type H in $G$ such that every element of $G$ appears an even number of times in the system of $\left\{D_{1}, D_{2}, D_{3}, D_{4}\right\}$. Let

$$
A_{1}=D_{1} \cap D_{2} \cap D_{3} \cap D_{4}, A_{5}=\bar{D}_{1} \cap \bar{D}_{2} \cap \bar{D}_{3} \cap \bar{D}_{4}
$$

$$
\begin{aligned}
& A_{2}=\left(D_{1} \cap D_{2}\right) \backslash A_{1}, A_{6}=\left(D_{3} \cap D_{4}\right) \backslash A_{1}, \\
& A_{3}=\left(D_{1} \cap D_{3}\right) \backslash A_{1}, A_{7}=\left(D_{2} \cap D_{4}\right) \backslash A_{1}, \\
& A_{4}=\left(D_{1} \cap D_{4}\right) \backslash A_{1}, A_{6}=\left(D_{2} \cap D_{3}\right) \backslash A_{1} .
\end{aligned}
$$

Let $\lambda_{x}$ be the number of times that the element $x \in G$ appears in the system of $\left\{D_{1}, D_{2}, D_{3}, D_{4}\right\}$. We know that $\lambda_{x}$ is either 0,2 or 4 : we have the following cases:

- If $\lambda_{x}=0$ then $x \in A_{5}$ and $x \notin A_{i}$ for all $1 \leq i \leq 8, i \neq 5$.
- If $\lambda_{x}=4$ then $x \in A_{1}$ and $x \notin A_{i}$ for all $1 \leq i \leq 8, i \neq 1$.
- If $\lambda_{x}=2$ without loss of generality consider that $x \in D_{1}$ and $x \in D_{2}$. Since $\lambda_{x}=2$ we know that $x \notin D_{3}$ and $x \notin D_{4}$ thus $x \in A_{2}$ and $x \notin A_{i}$ for all $1 \leq i \leq 8, i \neq 2$.

So for any element $x$ of $G$ we can say that $x$ is exactly in one of the subscts $A_{i}$, $i=1, \ldots, 8$. So we have

$$
\begin{gathered}
A_{i} \cap A_{j}=\emptyset, \text { for } i \neq j, 1 \leq i . j \leq 8, \\
\cup_{i=1}^{8} A_{i}=G .
\end{gathered}
$$

Thus the subsets $\left(A_{1} \ldots A_{8}\right)$ satisfy the first two conditions of Definition 2.18. Now we show that they satisfy the last condition too. It is clear that:

$$
\begin{aligned}
& D_{1}=A_{1} \cup A_{2} \cup A_{3} \cup A_{4}, \\
& D_{2}=A_{1} \cup A_{2} \cup A_{7} \cup A_{8}, \\
& D_{3}=A_{1} \cup A_{6} \cup A_{3} \cup A_{8}, \\
& D_{4}=A_{1} \cup A_{6} \cup A_{7} \cup A_{4} .
\end{aligned}
$$

From 2.15 we have

$$
\begin{aligned}
v \theta+\left(\sum_{i=1}^{4}\left|D_{i}\right|-v\right) T & =\sum_{i=1}^{4} \Delta D_{i} \\
& =\Delta\left(A_{1}, G\right)-\Delta\left(A_{5}, G\right)+\sum_{i=1}^{8} A_{i}-\sum_{i=1}^{4} \Delta\left(A_{i}, A_{i+4}\right)-\Delta G \\
& =\left(2\left(\left|A_{1}\right|-\left|A_{5}\right|\right)+v\right) T+\sum_{i=1}^{8} A_{i}-\sum_{i=1}^{4} \Delta\left(A_{i}, A_{i+4}\right) \\
& =\left(\sum_{i=1}^{4}\left|D_{i}\right|-v\right) T+\sum_{i=1}^{8} A_{i}-\sum_{i=1}^{4} \Delta\left(A_{i}, A_{i+4}\right)
\end{aligned}
$$

So we have:

$$
\sum_{i=1}^{8} \Delta A_{i}=v \theta+\sum_{i=1}^{4} \Delta\left(A_{i}, A_{i>4}\right)
$$

Thus $\left(A_{1}, \ldots, A_{8}\right)$ satisfies the condition (iii) of 2.18 and the proof is complete.
Theorem 2.20 If there is a $C$-partition $\left(A_{1}, \ldots, A_{8}\right)$ of an abelian group $G$ of order $v$ then there are $T$-matrices of order $v$.

Proof Let

$$
T_{i}=\left[t_{j k}^{(i)}\right], i=1,2,3,4,1 \leq j, k \leq v,
$$

where

$$
t_{j k}^{(i)}=\left\{\begin{array}{lll}
1, & \text { if } & g_{k} \ominus g_{j} \in A_{i}, \\
-1, & \text { if } & g_{k} \ominus g_{j} \in A_{i+4} \\
0, & \text { otherwise } .
\end{array}\right.
$$

It is not hard to see that:

- The matrices $T_{i}$ are type one matrices;
- $T_{i} \cap T_{j}=0 ;$
- $\sum_{i}\left|T_{i}\right|=J$.

To complete the proof we have to show that $\sum_{i=1}^{4} T_{i} T_{i}^{t}=v I$. It is sufficient to show that $\left[\sum_{i=1}^{4} T_{i} T_{i}^{t}\right]_{j j^{\prime}}=0$ for $1 \leq j, j^{\prime} \leq v, j \neq j^{\prime}$. We count the number of times that $t_{j k}^{(i)} t_{j^{\prime} k}^{(i)}=1$ and $t_{j k}^{(i)} t_{j^{\prime} k}^{(i)}=-1$ for fixed $j$ and $j^{\prime}$ such that $j \neq j^{\prime}, i=1,2,3,4$, and $k=1, \ldots, v$. If $t_{j k}^{(i)}=1$ and $t_{j^{\prime} k}^{(i)}=1$ we have $g_{k} \ominus g_{j} \in A_{i}$ and $g_{k} \ominus g_{j^{\prime}} \in A_{i}$. Since $\left(g_{k} \ominus g_{j}\right) \ominus\left(g_{k} \ominus g_{j^{\prime}}\right)=g_{j^{\prime}} \ominus g_{j}$ we see that the number of times that $t_{j k}^{(i)}=1$ and $t_{j^{\prime} k}^{(i)}=1$ is equal to the coefficient of $g_{j^{\prime}} \ominus g_{j}$ in $\Delta A_{i}$ for a fixed $i$. Similarly we can show that the number of times that $t_{j k}^{(i)}=-1$ and $t_{j^{\prime} k}^{(i)}=-1$ is equal to the coefficient of $g_{j^{\prime}} \theta g_{j}$ in $\Delta A_{i+4}$ for a fixed $i$. Thus the number of times that $t_{j k}^{(i)} t_{j^{\prime} k}^{(i)}=1$ for $i=1,2,3,4$ is equal to the coefficient of $g_{j^{\prime}} \ominus g_{j}$ in $\sum_{i=1}^{8} \Delta A_{i}$. By the same argument one can say that the number of times that $t_{j k}^{(i)} t_{j^{\prime} k}^{(i)}=-1$ for $i=1,2: 3,4$ is equal to the coefficient of $g_{j^{\prime}} \ominus g_{j}$ in $\sum_{i=1}^{4} \Delta\left(A_{i}, A_{i+4}\right)$. So using

$$
\sum_{i=1}^{8} \Delta A_{i}-\sum_{i=1}^{4} \Delta\left(A_{i}, A_{i+4}\right)=v \theta
$$

we have

$$
\sum_{i=1}^{4} T_{i} T_{i}^{t}=v I
$$

Theorem 2.21 If $q=8 m+3$ is a prime power then there are $T$-matrices of order $v=q^{2}$.

Proof By Theorems 2.17, 2.19, and 2.20 we can produce $T$-matrices of order $q^{2}$ where $q=8 m+3$ is a prime power.

## Chapter 3

## Productive Regular Hadamard Matrices and Symmetric Designs

### 3.1 Introduction

One of the most outstanding results in the production of many new symmetric designs belongs to Yury Ionin.

The use of a special regular Hadamard matrix of order 36 in a class of balanced generalised weighing matrices was initiated by Ionin in [5] and this was the beginning of a number of very successful papers like [5], [4]; [7], and [6] in which many new classes of symmetric designs were introduced. The hardest part of Ionin's construction was the introduction of a group of symmetry related to each single design. Hadi Kharaghani in [10] reintroduced the class of Bush-type Hadamard matrices and demonstrated that the group of symmetry for these matrices was trivial. Furthermore, it was through these works that he was led to twin designs [10] and Siamese twin designs [9]. In a recent work Yury Ionin introduced the class of productive regular Hadamard matrices. His method is now applied straight to Hadamard matrices. In this chapter we will introduce Bush-type Hadamard matrices and productive regular Hadamard matrices and show that Bush-type Hadamard matrices are productive. The methods used here borrow from both Ionin and Kharaghani.

We first need to introduce balanced generalised weighing matrices. We begin with a definition.

Definition 3.1 Let $G$ be a multiplicatively written group. A balanced generalised weighing matrix $B G W(v, k, \lambda)$ is a matrix $W=\left[w_{i j}\right]$ of order $v$ with $w_{i j} \in G \cup\{0\}$ such that each row and each column of $W$ contains exactly $k$ non-zero entries and for any $h \neq i$, the multiset $\left\{w_{h j} w_{i j}^{-1}: 1 \leq j \leq v, w_{h j} \neq 0, w_{i j} \neq 0\right\}$ contains exactly $\lambda /|G|$ copies of every element of $G$.

Here we explain Gerald Berman's method [2] to show that a specific class of balanced generalised weighing matrices exists.

Definition 3.2 Let $m$ be a positive integer and $q$ be a prime power. The affine geometry of dimension $m$ over the field $F_{q}=G F(q)$, denoted $A G(m, q)$ is the vector space $\left(F_{q}\right)^{m}$. The points of $A G(m, q)$ are $m$-tuples $x=\left(x_{1}, \ldots, x_{m}\right), x_{i} \in F_{q}$ and hyper-planes of $A G(m, q)$ are the set of points that satisfy

$$
u_{1} x_{1}+\cdots+u_{m} x_{m}=u, \quad u, u_{i} \in F_{q} .
$$

Theorem 3.3 (Berman 1978) If $q$ is a prime power and $G$ is a cyclic group such that the order of $G$ divides $q-1$ then there is a

$$
B G W\left(\left(q^{m}-1\right) /(q-1), q^{m-1}, q^{m-1}-q^{m-2}\right)
$$

over $G$, for every positive integer $m$.
Proof Let $E=A G(m, q)$ and let $P$ be the set of points of $E$ on removing a point $p$. We have $|P|=q^{m}-1$ and let $H$ be the set of those hyper-planes of $E$ that do not include the point $p$. Without loss of generality let $p=(0,0, \ldots, 0)$, then every hyper-plane of $u \in H$ can be expressed by the linear equation $u_{1} x_{1}+\cdots+u_{m} x_{m}=1$ where the coefficients $u_{i}, i=1, \ldots, m$ are not all zero. Thus every hyper-plane $u \in H$ can be expressed by an $m$-tuple $u=\left(u_{1}, \ldots, u_{m}\right)$; $u_{i} \in \operatorname{GF}(q), i=1, \ldots, m$. Using this notation it is clear that $|H|=q^{m}-1$. A point $x \in P$ is on a hyper-plane $u \in H$ if and only if $x \cdot u=1$. In order to count the number of points on a hyper-plane $u=\left(u_{1}, \ldots, u_{m}\right)$, if one fixes the first $m-1$ coordinates of $x=\left(x_{1}, \ldots, x_{m}\right)$ then one can find $x_{m}$ such that $x \cdot u=1$ and it follows that every hyper-plane has $q^{m-1}$ points and every point is on $q^{m-1}$ hyper-planes. Let $\lambda$ be an element of $\operatorname{GF}(q)$ of order $q-1$, define the map $\phi_{\lambda}: P \rightarrow P$ such that

$$
\phi_{\lambda} x=\lambda x=\left(\lambda x_{1}, \ldots, \lambda x_{m}\right)
$$

Let $x$ be a point on a hyper-plane $u$. Since $(\lambda x) \cdot\left(\lambda^{-1} u\right)=1, \phi_{\lambda}$ maps the hyper-plane $u$ onto $\lambda^{-1} u$ and we have $\phi_{\lambda} u=\lambda^{-1} u$. It is clear that the order of $\phi_{\lambda}$ is $q-1$. As every point $x \in P$ or every hyper-plane $u \in H$ has at least one non-zero coordinate the map $\phi_{\lambda}$ has no fixed point or fixed hyper-plane. Let

$$
\begin{array}{ll}
{[x]=\left\{\phi_{\lambda}^{k} x: k=0, \ldots, q-1\right\},} & x \in P \\
{[u]=\left\{\phi_{\lambda}^{k} u: k=0, \ldots, q-1\right\},} & u \in H .
\end{array}
$$

It is clear that $y \in[x]$ if and only if $x \in[y]$ so one can choose the points $x^{1}, x^{2}, \ldots, x^{n} \in$ $P, n=\left(q^{m}-1\right) /(q-1)$ such that $\left[x^{1}\right] \cup\left[x^{2}\right] \cup \ldots \cup\left[x^{n}\right]$ is a partition of $P$ and hyperplanes $u^{1}, u^{2}, \ldots, u^{n} \in H$ such that $\left[u^{1}\right\} \cup\left[u^{2}\right] \cup \ldots \cup\left[u^{n}\right]$ is a partition of $H$. Since the hyper-planes $\phi_{\lambda}^{k} u^{i}$ are parallel, the point $x^{j}$ lies on at most one of them. If $x^{j}$ is a point of $\phi_{\lambda}^{l} u^{i}$ then $\phi_{\lambda}^{k} x^{j}$ is a point of $\phi_{\lambda}^{l+k} u^{i}$ so we can write $\left.\left[x^{j}\right] \in u^{i}\right]$ if the points of $\left[x^{j}\right]$ lie on the hyper-planes of $\left[u^{i}\right]$. If $\left[x^{j}\right] \in\left[u^{i}\right]$ then there is a unique integer $h=\nu\left(u^{i}, x^{j}\right)$ such that $\phi_{\lambda}^{h} x^{j} \in u^{i}$. Let $G$ be a multiplicatively written cyclic group of order $d$ such that $d \mid q-1$ and let $\omega$ be a generator of $G$. Let $A=A\left(\phi_{\lambda}, x^{1}, \ldots, x^{n}, u^{1}, \ldots, u^{n}, \omega\right)$ denote the $n \times n$ matrix $a_{i j}$ defined by

$$
a_{i j}= \begin{cases}\omega^{\nu\left(u^{i}, x^{3}\right)} & \text { if }\left[x^{j}\right] \in\left[u^{i-}\right.  \tag{3.1}\\ 0 & \text { otherwise }\end{cases}
$$

for $i=1, \ldots, n$.
To complete the proof we show that $A$ is a $B G W\left(\left(q^{m}-1\right) /(q-1), q^{m-1}, q^{m-1}-q^{m-2}\right)$ over $G$. Since every hyper-plane has $q^{m-1}$ points every row of $A$ has exactly $q^{m-1}$ nonzero entries. Since $\left(q^{m}-1\right) /(q-1)-q^{m-1}<q^{m-1}$ any two different rows of $A$ have at least one point in common and for $i \neq k, u^{i}$ and $u^{k}$ are not parallel. Consider two hyper-planes $u^{i}=\left(u_{1}^{i}, \ldots, u_{m}^{i}\right)$ and $u^{k}=\left(u_{1}^{k}, \ldots, u_{m}^{k}\right)$ that are not parallel. There are integers $1 \leq e<f \leq m$ such that $u_{e}^{i} / u_{e}^{k} \neq u_{f}^{i} / u_{f}^{k}$. If the point $x=\left(x_{1}, \ldots, x_{m}\right)$ is on both hyper-planes $u^{i}$ and $u^{k}$ then by fixing the coordinates $x_{t}, t \neq e, f$ one can find the proper $x_{e}$ and $x_{f}$ that satisfy the equations $x \cdot u^{i}=1$ and $x \cdot u^{k}=1$. So if $u^{i}$ and $u^{k}$ are not parallel they have $q^{m-2}$ points in common. Thus $u^{i}$ intersects each of the hyper-planes $\phi_{\lambda}^{h} u^{k}, h=0, \ldots, q-1$ in $q^{m-2}$ points and the multiset $\left\{a_{i j} a_{k j}^{-1}: 1 \leq j \leq\right.$ $\left.n, a_{i j} \neq 0, a_{k j} \neq 0\right\}$ contains exactly $(q-1) q^{m-2}=q^{m-1}-q^{m-2}$ non-zero elements.

For any point $\phi_{\lambda}^{l} x^{j}$ on $u^{i}$ and $\phi_{\lambda}^{h} u^{k}$ we have

$$
u^{i}\left(\phi_{\lambda}^{l} x^{j}\right)=1, \quad\left(\phi_{\lambda}^{h} u^{k}\right)\left(\phi_{\lambda}^{l} x^{j}\right)=u^{k}\left(\phi_{\lambda}^{l-h} x^{j}\right)=1
$$

so $\nu\left(u^{i}, x^{j}\right)=l, \nu\left(u^{k}, x^{j}\right)=l-h$ and $a_{i j} a_{k j}^{-1}=\omega^{h}$ for $h=0, \ldots, q-1$ so the multiset $\left\{a_{i j} a_{k j}^{-1}: 1 \leq j \leq n, a_{i j} \neq 0, a_{k j} \neq 0\right\}$ contains exactly $q^{m-2}$ times of each element $\omega^{h}$ and this completes the proof.

Definition 3.4 A regular Hadamard matrix $H$ with row sum $2 h$ is productive if there is a set $\mathcal{H}$ of matrices with row sum $2 h$ and a cyclic group $G=\langle\delta\rangle$ where $\delta: \mathcal{H} \rightarrow \mathcal{H}$ is a bijection, such that
(i) $H \in \mathcal{H}$;
(ii) For any $H_{1}, H_{2} \in \mathcal{H},\left(\delta H_{1}\right)\left(\delta H_{2}\right)^{t}=H_{1} H_{2}^{t}$;
(iii) $|G|=4|h|$;
(iv) $\sum_{\sigma \in G} \sigma H=2 \frac{h}{|h|} J$.

Lemma 3.5 If $H$ is productive then $-H$ is also productive.
Proof The proof is straightforward.
Theorem 3.6 (Ionin) If there is a productive regular Hadamard matrix $H$ with row sum $2 h$ and $q=(2 h-1)^{2}$ is a prime power then for any positive integer $m$ there is a symmetric design with parameters:

$$
\left(\frac{4 h^{2}\left(q^{m+1}-1\right)}{q-1},\left(2 h^{2}-h\right) q^{m},\left(h^{2}-h\right) q^{m}\right) .
$$

Proof Let $W=\left[w_{i j}\right]$ be a $B G W\left(\left(q^{m+1}-1\right) /(q-1), q^{m}, q^{m}-q^{m i-1}\right)$ over $G$ and let

$$
M=\frac{1}{2}(J-H) .
$$

We know that $M$ is the incidence matrix of a symmetric ( $4 h^{2}, 2 h^{2}-h, h^{2}-h$ )-design. If $H_{1} \in \mathcal{H}, M_{1}=\frac{1}{2}\left(J-H_{1}\right)$, and $\delta \in G$ we definc:

$$
\delta M_{1}=\frac{1}{2}\left(J-\delta H_{1}\right) .
$$

If $H_{1}, H_{2} \in \mathcal{H}, M_{1}=\frac{1}{2}\left(J-H_{1}\right)$, and $M_{2}=\frac{1}{2}\left(J-H_{2}\right)$ we have:

$$
\begin{aligned}
\left(\delta M_{1}\right)\left(\delta M_{2}\right)^{t} & =\frac{1}{4}\left(J-\delta H_{1}\right)\left(J-\delta H_{2}\right)^{t} \\
& =\frac{1}{4}\left(J^{2}-\left(\delta H_{1}\right) J-J\left(\delta H_{2}\right)^{t}+\left(\delta H_{1}\right)\left(\delta H_{2}\right)^{t}\right) \\
& =\frac{1}{4}\left(J^{2}-H_{1} J-J H_{2}^{t}-H_{1} H_{2}^{t}\right) \\
& =M_{1} M_{2}^{t} .
\end{aligned}
$$

It can also easily be seen that $\sum_{\delta \in G} \delta M=\left(2|h|-\frac{h}{i h \mid}\right) J$. We prove that $W \otimes M$ is the incidence matrix of a symmetric $\left(4 h^{2}\left(q^{m+1}-1\right) /(q-1),\left(2 h^{2}-h\right) q^{m} \cdot\left(h^{2}-h\right) q^{m}\right)-$ design. It suffices to show that for $i, j=1,2, \ldots,\left(q^{m+1}-1\right) /(q-1)$,

$$
\sum_{k=1}^{\left(q^{m+1}-1\right) /(q-1)}\left(w_{i k} M\right)\left(w_{j k} M\right)^{t}= \begin{cases}h^{2} q^{m} I+\left(h^{2}-h\right) q^{m} J & \text { if } \mathrm{i}=\mathrm{j}, \\ \left(h^{2}-h\right) q^{m} J & \text { otherwise } .\end{cases}
$$

If $i=j$ then for some $\delta_{k} \in G$ we have:

$$
\begin{aligned}
\sum_{k=1}^{\left(q^{m+1}-1\right) /(q-1)}\left(w_{i k} M\right)\left(w_{j k} M\right)^{t} & =\sum_{k=1}^{q^{m}}\left(\delta_{k} M\right)\left(\delta_{k} M\right)^{t} \\
& =\sum_{k=1}^{q^{m}} M M^{t} \\
& =q^{m} M M^{t} \\
& =h^{2} q^{m} I+\left(h^{2}-h\right) q^{m} J .
\end{aligned}
$$

If $i \neq j$ then for some $\delta_{k}, \tau_{k} \in G$,

$$
\begin{aligned}
\sum_{k=1}^{\left(q^{m+1}-1\right) /(q-1)}\left(w_{i k} M\right)\left(w_{j k} M\right)^{t} & =\sum_{k=1}^{q^{m}-q^{m-1}}\left(\delta_{k} M\right)\left(\tau_{k} M\right)^{t} \\
& =\sum_{k=1}^{q^{m}-q^{m-1}}\left(\tau_{k}^{-1} \delta_{k} M\right) M^{t} \\
& =\frac{q^{m}-q^{m-1}}{4|h|}\left(\sum_{\sigma \in G} \sigma M\right) M^{t} \\
& =\frac{q^{m}-q^{m-1}}{4|h|}\left(2|h|-\frac{h}{|h|}\right) J M^{t} \\
& =\frac{q^{m}-q^{m-1}}{4|h|}\left(2|h|-\frac{h}{|h|}\right)\left(2 h^{2}-h\right) J \\
& =\frac{1}{4}\left(q^{m}-q^{m-1}\right) q J=q^{m}\left(h^{2}-h\right) J .
\end{aligned}
$$

### 3.2 Bush-type Hadamard matrices

Definition 3.7 A regular Hadamard matrix $H=\left[H_{i j}\right]$ of order $4 n^{2}$ where $H_{i j}$ are blocks of order $2 n$ is Bush-type if $H_{i i}=J_{2 n}$ and $H_{i j} J_{2 n}=J_{2 n} H_{i j}=0$, for $i \neq j$, $1 \leq i, j \leq 2 n$.

We will now show that there are many Bush-type Hadamard matrices and each Bushtype Hadamard matrix is a productive regular Hadamard matrix.

Theorem 3.8 (Kharaghani 1985 [8]) If there is a Hadamard matrix of order $4 n$ then there is a Bush-type Hadamard matrix of order $16 n^{2}$.

Proof Let $K$ be a normalised Hadamard matrix of order $4 n$ and let $r_{1}, r_{2}, \ldots, r_{4 n}$ be the rows of $K$. Let $C_{i}=r_{i}^{t} r_{i}, i=1, \ldots, 4 n$. It is easy to see that:
(i) $C_{i}=C_{i}^{t}$ for $i=1,2, \ldots, 4 n$;
(ii) $C_{1}=J_{4 n}, C_{i} J_{4 n}=J_{4 n} C_{i}=0$; for $i=1, \ldots, 4 n$;
(iii) $C_{i} C_{j}^{t}=0$ if $i \neq j$;
(iv) $\sum_{i=1}^{4 n} C_{i} C_{i}^{t}=16 n^{2} I_{4 n}$.

Following Seberry, Yamada [14], we call the matrices $C_{i}$ above as Kharaghani matrices. Let $H=\operatorname{circ}\left(C_{1}, C_{2}, \ldots, C_{4 n}\right)$ then $H$ is a Bush-type Hadamard matrix of order $16 n^{2}$. $\square$

Example 3. Let

$$
K=\left[\begin{array}{cccc}
1 & 1 & 1 & 1 \\
1 & 1 & - & - \\
1 & - & 1 & - \\
1 & - & - & 1
\end{array}\right]
$$

Then,

$$
\begin{aligned}
& r_{1}=\left[\begin{array}{llll}
1 & 1 & 1 & 1
\end{array}\right] \\
& r_{2}=\left[\begin{array}{llll}
1 & 1 & - & -
\end{array}\right] \\
& r_{3}=\left[\begin{array}{llll}
1 & - & 1 & -
\end{array}\right] \\
& r_{4}=\left[\begin{array}{llll}
1 & - & 1 & ] \\
C_{1} & =r_{1}^{t} r_{1}=\left[\begin{array}{llll}
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1
\end{array}\right] \\
C_{2}=r_{2}^{t} r_{2}=\left[\begin{array}{llll}
1 & 1 & - & - \\
1 & 1 & - & - \\
- & - & 1 & 1 \\
- & - & 1 & 1
\end{array}\right] \\
C_{3}=r_{3}^{t} r_{3}=\left[\begin{array}{cccc}
1 & - & 1 & - \\
- & 1 & - & 1 \\
1 & - & 1 & - \\
- & 1 & - & 1
\end{array}\right] \\
C_{4}=r_{4}^{t} r_{4}=\left[\begin{array}{llll}
1 & - & - & 1 \\
- & 1 & 1 & - \\
- & 1 & 1 & - \\
1 & - & - & 1
\end{array}\right]
\end{array}{ }_{39} \quad \begin{array}{lll}
\end{array}\right]
\end{aligned}
$$

$$
B=\left[\begin{array}{cccccccccccccccc}
1 & 1 & 1 & 1 & 1 & 1 & - & - & 1 & - & 1 & - & 1 & - & - & 1 \\
1 & 1 & 1 & 1 & 1 & 1 & - & - & - & 1 & - & 1 & - & 1 & 1 & - \\
1 & 1 & 1 & 1 & - & - & 1 & 1 & 1 & - & 1 & - & - & 1 & 1 & - \\
1 & 1 & 1 & 1 & - & - & 1 & 1 & - & 1 & - & 1 & 1 & - & - & 1 \\
1 & - & - & 1 & 1 & 1 & 1 & 1 & 1 & 1 & - & - & 1 & - & 1 & - \\
- & 1 & 1 & - & 1 & 1 & 1 & 1 & 1 & 1 & - & - & - & 1 & - & 1 \\
- & 1 & 1 & - & 1 & 1 & 1 & 1 & - & - & 1 & 1 & 1 & - & 1 & - \\
1 & - & - & 1 & 1 & 1 & 1 & 1 & - & - & 1 & 1 & - & 1 & - & 1 \\
1 & - & 1 & - & 1 & - & - & 1 & 1 & 1 & 1 & 1 & 1 & 1 & - & - \\
- & 1 & - & 1 & - & 1 & 1 & - & 1 & 1 & 1 & 1 & 1 & 1 & - & - \\
1 & - & 1 & - & - & 1 & 1 & - & 1 & 1 & 1 & 1 & - & - & 1 & 1 \\
- & 1 & - & 1 & 1 & - & - & 1 & 1 & 1 & 1 & 1 & - & - & 1 & 1 \\
1 & 1 & - & - & 1 & - & 1 & - & 1 & - & - & 1 & 1 & 1 & 1 & 1 \\
1 & 1 & - & - & - & 1 & - & 1 & - & 1 & 1 & - & 1 & 1 & 1 & 1 \\
- & - & 1 & 1 & 1 & - & 1 & - & - & 1 & 1 & - & 1 & 1 & 1 & 1 \\
- & - & 1 & 1 & - & 1 & - & 1 & 1 & - & - & 1 & 1 & 1 & 1 & 1
\end{array}\right]
$$

Theorem 3.9 Bush-type Hadamard matrices are productive.
Proof Let $H=\left[H_{i j}\right], 1 \leq i, j \leq 2 n$ be a Bush-type Hadamard matrix of order $4 n^{2}$ with block size $2 n$, and let $\mathcal{H}$ be a family of block matrices $X=\left[X_{i j}\right], 1 \leq i, j \leq 2 n$ of order $4 n^{2}$, satisfying the following conditions:
(i) for each $i$ there is exactly one block $X_{i j 0}$ such that $X_{i j o}=J_{2 n}$ :
(ii) if $j \neq j_{0}$ then $X_{i j} J=J X_{i j}=0$.

It is clear that $H \in \mathcal{H}$. We define a bijection $\sigma: \mathcal{H} \rightarrow \mathcal{H}$ by $\sigma X=X^{\prime}$ such that:
(i) for $1 \leq i \leq 2 n$ and $2 \leq j \leq 2 n, X_{i j}^{\prime}=X_{i, j-1}$;
(ii) for $1 \leq i \leq 2 n$ if $X_{i, 2 n}=J$, then $X_{i 1}^{\prime}=J$;
(iii) for $1 \leq i \leq 2 n$ if $X_{i, 2 n} J=J X_{i, 2 n}=0$, then $X_{i 1}^{\prime}=-X_{i, 2 n}$.

Let $G=<\sigma>$ then it is clear that $|G|=4 n$.
Let $P, Q \in \mathcal{H}$ and let $P^{\prime}=\sigma P$ and $Q^{\prime}=\sigma Q$, to show that $(\sigma P)(\sigma Q)^{t}=P Q^{l}$ it is enough to show that

$$
P_{i, 2 n} Q_{j, 2 n}^{t}=P_{i 1}^{\prime} Q_{j 1}^{\prime t} .
$$

There are four cases:

1. If $P_{i, 2 n}=J$ and $Q_{j, 2 n}=J$ then $P_{i 1}^{\prime}=J$ and $Q_{j 1}^{\prime}=J$ so $P_{i, 2 n} Q_{j, 2 n}^{t}=P_{i 1}^{\prime} Q_{j 1}^{\prime}=J^{2}$.
2. If $P_{i, 2 n} J=J P_{i, 2 n}=0$ and $Q_{j, 2 n}=J$ then $P_{i 1}^{\prime}=-P_{i, 2 n}$ and $Q_{j 1}^{\prime}=J$ so $P_{i, 2 n} Q_{j, 2 n}^{t}=P_{i, 2 n} J=0$ and $P_{i 1}^{\prime} Q_{j 1}^{\prime t}=-P_{i, 2 n} J=0$.
3. If $P_{i, 2 n}=J$ and $Q_{j, 2 n} J=J Q_{i, 2 n}=0$ then $P_{i 1}^{\prime}=P_{i, 2 n}=J$ and $Q_{j 1}^{\prime}=-Q_{j, 2 n}$ so $P_{i, 2 n} Q_{j, 2 n}^{t}=J Q_{j, 2 n}^{t}=0$ and $P_{i 1}^{\prime} Q_{j 1}^{\prime t}=-J Q_{j, 2 n}^{t}=0$.
4. If $P_{i, 2 n} J=J P_{i, 2 n}=0$ and $Q_{j, 2 n} J=J Q_{j, 2 n}=0$ then $P_{i 1}^{\prime}=-P_{i, 2 n}$ and $Q_{j 1}^{\prime}=$ $-Q_{j, 2 n}$ so $P_{i 1}^{\prime} Q_{j 1}^{\prime t}=\left(-P_{i, 2 n}\right)\left(-Q_{j, 2 n}\right)^{t}=P_{i, 2 n} Q_{j, 2 n}^{t}$.

Since also $\sum_{\delta \in G} \delta H=2 J$, the proof is complete.

Corollary 3.10 If there is a Bush-type Hadamard matrix of order $4 n^{2}$ and $q=(2 n-$ $1)^{2}$ is a prime power then for every positive integer $m$ there is a symmetric design with parameters

$$
\begin{equation*}
\left(\frac{4 n^{2}\left(q^{m+1}-1\right)}{q-1}, q^{m}\left(2 n^{2}-n\right), q^{m}\left(n^{2}-n\right)\right) \tag{3.2}
\end{equation*}
$$

and if $q=(2 n+1)^{2}$ is a prime power then for every positive integer $m$ there is a symmetric design with parameters

$$
\begin{equation*}
\left(\frac{4 n^{2}\left(q^{m+1}-1\right)}{q-1}, q^{m}\left(2 n^{2}+n\right), q^{m}\left(n^{2}+n\right)\right) \tag{3.3}
\end{equation*}
$$

Proof Suppose that $H$ is a Bush-type Hadamard matrix of order $4 n^{2}$. For the case where $q=(2 n-1)^{2}$, since the matrix $H$ has row sum $2 n$, the proof follows from Theorems 3.6 and 3.9. For the case where $q=(2 n+1)^{2}$, since the matrix $-H$ has row sum $-2 n$, the proof follows from Lemma 3.5. Theorem 3.6, and Theorem 3.9.

Theorem 3.8 shows that the existence of a Hadamard matrix of order $4 n$ implies the existence of a Bush-type Hadamard matrix of order $16 n^{2}$. It has been conjectured that Bush-type Hadamard matrices of order $4 n^{2}$ exist for all integers $n$. For odd values of $n$ this conjecture seems to be difficult and only known for $n=3,5$, and 9 .

### 3.3 The Kronecker product of Bush-type Hadamard matrices and productive regular Hadamard matrices

Ionin in a recent paper [4] showed that the Kronecker product of a Bush-type Hadamard matrix $B$ and a productive regular Hadamard matrix $H$ namely $M=B \otimes H$ is also a productive regular Hadamard matrix. In this section we introduce his method.

Let $B$ be a Bush-type Hadamard matrix of order $4 n^{2}$ and let $H$ be a productive regular Hadamard matrix with row sum $2 h$ and cyclic group $G=\langle\delta\rangle$. Let

$$
\mathcal{H}=\left\{\delta^{i} H|i=0,1, \ldots, 4| h \mid-1\right\} .
$$

By the definition we have:

- For any $H_{1}$ and $H_{2}$ in $\mathcal{H},\left(\delta H_{1}\right)\left(\delta H_{2}\right)^{t}=H_{1} H_{2}^{t}$;
- $\sum_{X \in \mathcal{H}} X=2 \frac{h}{|h|} J$.

Let $\mathcal{Z}=\{Z \mid Z J=J Z=0\}, \mathcal{R}=\{J \otimes K \mid K \in \mathcal{H}\}$, and $\mathcal{S}=\{Z \otimes H \mid Z \in \mathcal{Z}\}$, where $J$ and $Z$ are of order $2 n$. We define the map $\rho: \mathcal{R} \cup \mathcal{S} \rightarrow \mathcal{R} \cup \mathcal{S}$ by

$$
\begin{array}{rlrl}
\rho(Z \otimes H) & =-Z \otimes H & \text { for each } & Z \in \mathcal{Z} \\
\rho(J \otimes K) & =J \otimes(\delta K) & \text { for each } & \\
& K \in \mathcal{H} .
\end{array}
$$

It is easy to see that the cyclic group generated by $\rho$ has order $4|h|$. For $R \in \mathcal{R}$ we
have:

$$
\begin{aligned}
\sum_{i=0}^{4|H|} \rho^{i} R & =\sum_{i=0}^{4|h|} \rho^{i} J \otimes \delta^{j} H \\
& =\sum_{i=0}^{4|h|} J \otimes\left(\delta^{i+j} H\right) \\
& =\sum_{i=0}^{4 i h \mid} J \otimes\left(\delta^{i} H\right) \\
& =J \otimes\left(\sum_{i=0}^{4|h|} \delta^{i} H\right) \\
& =J \otimes\left(2 \frac{h}{|h|} J\right) \\
& =2 \frac{h}{|h|} J \otimes J
\end{aligned}
$$

For $S \in \mathcal{S}$ it is easy to see that

$$
\sum_{i=0}^{4|h|} \rho^{i} S=0
$$

Let $M=B \otimes H$. It is clear that the matrix $M$ is a regular Hadamard matrix with row sum $4 h n$. Let $\mathcal{M}$ be the set of block matrices $D=\left[D_{i j}\right], i, j=1, \ldots, 2 n$, such that:

1. for each $i=1, \ldots, 2 n$, there is a unique $h_{i}=h_{i}(D) \in\{1, \ldots, 2 n\}$, such that for $j=h_{i}, D_{i j} \in \mathcal{R} ;$
2. for $i=1, \ldots, 2 n$, and for $j \neq h_{i}, D_{i j} \in \mathcal{S}$.

Clearly $M$ is an element of $\mathcal{M}$. Define a bijection $\sigma: \mathcal{M} \rightarrow \mathcal{M}$ by $\sigma D=D^{\prime}=\left[D_{i j}^{\prime}\right]$ such that:

1. for $i=1, \ldots, 2 n$, and $j=2, \ldots, 2 n, D_{i j}^{\prime}=D_{i, j-1}$;
2. for $i=1, \ldots, 2 n, D_{i 1}^{\prime}=\rho D_{i, 2 n}$.

It follows from the fact that $\rho^{4|k|}=1$ and from the number of blocks of $D$ that the order of the cyclic group $G$ generated by $\sigma$ is $8 n|h|$.

Lemma 3.11 For $X, Y \in \mathcal{M},(\sigma X)(\sigma Y)^{t}=X Y^{t}$.
Proof Let $X, Y \in \mathcal{M}$ and let $X^{\prime}=\sigma X$ and $Y^{\prime}=\sigma Y$. It is sufficient to show that, for $i, i^{\prime}=1, \ldots, 2 n$,

$$
X_{i 1}^{\prime} Y_{i^{\prime} 1}^{\prime t}=X_{i, 2 n} Y_{i^{\prime}, 2 n}^{t}
$$

It is obvious that $X_{i, 2 n}$ and $Y_{i^{\prime}, 2 n}$ are either in $\mathcal{R}$ or in $\mathcal{S}$. We have to check the following cases:

- If $X_{i, 2 n} \in \mathcal{S}$ and $Y_{i^{\prime}, 2 n} \in \mathcal{S}$ then $X_{i 1}^{\prime} Y_{i^{\prime} 1}^{\prime t}=\left(-X_{i, 2 n}\right)\left(-Y_{i^{\prime}, 2 n}\right)^{t}=X_{i, 2 n} Y_{i^{\prime}, 2 n}^{t}$.
- If $X_{i, 2 n} \in \mathcal{R}$ and $Y_{i^{\prime}, 2 n} \in \mathcal{S}$ then for some $K \in \mathcal{H}$ and $Z \in \mathcal{Z}$ we have:

$$
\begin{aligned}
X_{i, 2 n} Y_{i^{\prime}, 2 n}^{t} & =(J \otimes K)\left(Z^{t} \otimes H^{t}\right) \\
& =\left(J Z^{t}\right) \otimes\left(K H^{t}\right) \\
& =0,
\end{aligned}
$$

and

$$
\begin{aligned}
X_{i 1}^{\prime} Y_{i^{\prime} 1}^{\prime t} & =(J \otimes(\delta K))\left(-Z^{t} \otimes H^{t}\right) \\
& =\left(-J Z^{t}\right) \otimes\left((\delta K) H^{t}\right) \\
& =0 .
\end{aligned}
$$

- The proof for the case $X_{i, 2 n} \in \mathcal{S}$ and $Y_{i^{\prime}, 2 n} \in \mathcal{R}$ is similar and we omit it.
- If $X_{i, 2 n} \in \mathcal{R}$ and $Y_{i^{\prime}, 2 n} \in \mathcal{R}$ then for some $K_{1}$ and $K_{2}$ in $\mathcal{R}$ we have:

$$
\begin{aligned}
X_{i 1}^{\prime} Y_{i^{\prime} 1}^{\prime t} & =\left(J \otimes\left(\delta K_{1}\right)\right)\left(J^{t} \otimes\left(\delta K_{2}\right)^{t}\right) \\
& =\left(J J^{t}\right) \otimes\left(\left(\delta K_{1}\right)\left(\delta K_{2}\right)^{t}\right) \\
& =\left(J J^{t}\right) \otimes\left(K_{1} K_{2}^{t}\right) \\
& =X_{i, 2 n} Y_{i^{\prime}, 2 n} .
\end{aligned}
$$

Lemma $3.12 \sum_{g=0}^{8 n|n|-1} \sigma^{g} H=2 J$.

Proof For some $R \in \mathcal{R}$ and $S_{k} \in \mathcal{S}, 1 \leq k \leq 2 n-1$, we see that the ( $i, j$ )-block of the matrix $\sum_{g=0}^{8 n| | h \mid-1} \sigma^{g} M$ is:

$$
\begin{aligned}
{\left[\sum_{l=0}^{8 n \mid h i-1} \sigma^{l} M\right]_{i j} } & =\sum_{\alpha=0}^{4|h|-1} \rho^{\alpha} R+\sum_{k=1}^{2 n-1} \sum_{\alpha=0}^{4|h|-1} \rho^{\alpha} S_{k} \\
& =2 \frac{h}{|h|} J+\sum_{k=1}^{2 n-1} 0 \\
& =2 \frac{h}{|h|} J .
\end{aligned}
$$

Theorem 3.13 Let $B$ be a Bush-type Hadamard matrix and $H$ be a productive regular Hadamard matrix then the matrix $M=B \otimes H$ is productive.

Proof Using Lemmas 3.11 and 3.12 we see that the matrix $M$, the set $\mathcal{M}$ and the bijection $\sigma$ satisfy all of the conditions of definition 3.4.

## Chapter 4

## A New Class of Productive Regular Hadamard Matrices

In this chapter we introduce a new class of productive regular Hadamard matrices. We show that for each integer $n$ for which $4 n$ is the order of a Hadamard matrix and $8 n^{2}-1$ is a prime, there is a productive regular Hadamard matrix of order $16 n^{2}\left(8 n^{2}-1\right)^{2}$. As a corollary, by applying a recent result of Ionin, we get many new infinite classes of symmetric designs provided that either $4 n\left(8 n^{2}-1\right)-1$, or $4 n\left(8 n^{2}-1\right) \div 1$ (or both) are prime powers.

### 4.1 Introduction

We begin this section by introducing a fascinating class of matrices, originally generated by Mathon [12] and subsequently generalised by Seberry and Whiteman [13].

Definition 4.1 $A$ regular $s$-set of matrices of order $m^{2}$ is a set of matrices $A_{1}, A_{2}$, ..., $A_{s}$ such that:

- $A_{i} A_{j}=J$, for every $i, j$;
- $A_{i} A_{j}^{t}=A_{j}^{t} A_{i}=J, \quad i \neq j ;$
- $A_{i} J=m J$, for every $i$,
- $\sum_{i=1}^{s}\left(A_{i} A_{i}^{t}+A_{i}^{t} A_{i}\right)=2 s m^{2} I$.

It is shown in Seberry and Whiteman [13] that:
Theorem 4.2 (Seberry-Whiteman) If $m \equiv 3(\bmod 4)$ is a prime power, then there is a regular $\frac{1}{2}(m+1)$-set of order $m^{2}$.

See Lemmas 4.5 and 4.6 for a proof of this theorem.

### 4.2 A regular class of Hadamard matrices

Let $K$ be a normalised Hadamard matrix of order $4 n$. Let $r_{1}, r_{2}, \ldots, r_{4 n}$ be the row vectors of $K$. Let $C_{i}=r_{i}^{t} r_{i}, i=1, \ldots, 4 n$, be Kharaghani matrices. These matrices can be used in a Latin square to generate a Bush-type Hadamard matrix of order $16 n^{2}$ (see Theorem 3.8 for details). For the matrices $C=\left[c_{i j}\right]$ and $D=\left\{d_{i j}\right]$, we denote the matrix $\left[c_{i j} d_{i j}\right]$ by $C * D$, whenever the product $c_{i j} d_{i j}$ is defined.

We are now ready for the main result of this section.

Theorem 4.3 Let $n$ be an integer for which there is a Hadamard matrix of order $4 n$ and $m=8 n^{2}-1$ be a prime power. Then there is a regular Hadamard matrix of order $16 n^{2} m^{2}$.

Proof Let $A_{i}, i=1,2, \cdots, 4 n^{2}$, be a regular $4 n^{2}-$ set of matrices of order $m^{2}$ from Theorem 4.2. Let

$$
L_{i}= \begin{cases}\operatorname{circ}\left(A_{4(i-1) n+1}, \ldots, A_{4 i n}\right) & \text { if } 1 \leq i \leq n \\ \operatorname{circ}\left(A_{4(i-n-1) n+1}^{t}, \ldots, A_{4(i-n) n}^{t}\right) & \text { if } n<i \leq 2 n\end{cases}
$$

Let $C_{i}$ s be Kharaghani matrices defined above. Let $K_{i}:=C_{i} * L_{i}$ and $K_{i}^{\prime}:=C_{i+2 n} * L_{i}$ for $1 \leq i \leq 2 n$. Using the properties of the regular $s$-set of matrices, it is not hard to see that the matrices $K_{i}$ and $K_{i}^{\prime}$ have the following properties for every $i$ and $j$ :

1. $K_{i} K_{j}^{t}=K_{i}^{\prime} K_{j}^{\prime t}=0$ if $i \neq j$
2. $K_{i} K_{j}^{\prime t}=K_{j}^{\prime} K_{i}^{t}=0$ if $i \neq j$
3. $K_{i} K_{i}^{\prime t}=K_{i}^{\prime} K_{i}^{t}$

Let $M=\operatorname{circ}\left(K_{1}, K_{2}, \ldots, K_{2 n}\right)$ and $M^{\prime}=\operatorname{circ}\left(K_{1}^{\prime}, K_{2}^{\prime}, \ldots, K_{2 n}^{\prime}\right)$. Let

$$
H=\left[\begin{array}{cc}
M & M^{\prime} \\
-M^{\prime} & M
\end{array}\right]
$$

Let $\epsilon$ be the column vector of all ones. The fact that $K_{1} e=4 n m$ and $K_{i} e=0$ for all $i$, $2 \leq i \leq 2 n$, implies that $M e=4 n m$. On the other hand, $K_{i}^{\prime} e=0$ for all $i, 1 \leq i \leq 2 n$, so $M^{\prime} e=0$. This shows that $H$ is a regular matrix of order $16 n^{2} m^{2}$. It remains to show that $H$ is a Hadamard matrix. Using properties 1 and 2 above, it is not hard to see that $M M^{t}$ and $M^{\prime} M^{\prime t}$ are both diagonal matrices. Furthermore, property 3 can be used to show that $M M^{t}=M^{\prime} M^{t}$. It is easy now to see that $H$ is a Hadamard matrix. $\square$

Example 4. For $n=1$ we have:

$$
\begin{gathered}
L_{1}=\left[\begin{array}{llll}
A_{1} & A_{2} & A_{3} & A_{4} \\
A_{4} & A_{1} & A_{2} & A_{3} \\
A_{3} & A_{4} & A_{1} & A_{2} \\
A_{2} & A_{3} & A_{4} & A_{1}
\end{array}\right] \\
L_{2}=\left[\begin{array}{llll}
A_{1}^{t} & A_{2}^{t} & A_{3}^{t} & A_{4}^{t} \\
A_{4}^{t} & A_{1}^{t} & A_{2}^{t} & A_{3}^{t} \\
A_{3}^{t} & A_{4}^{t} & A_{1}^{t} & A_{2}^{t} \\
A_{2}^{t} & A_{3}^{t} & A_{4}^{t} & A_{1}^{t}
\end{array}\right] \\
C_{1}
\end{gathered} \begin{aligned}
& C_{2}=\left[\begin{array}{llll}
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1 \\
1 & 1 & 1 & 1
\end{array}\right] \\
& 1
\end{aligned}
$$

$$
\begin{aligned}
& C_{3}=\left[\begin{array}{cccc}
1 & - & 1 & - \\
- & 1 & - & 1 \\
1 & - & 1 & - \\
- & 1 & - & 1
\end{array}\right] \\
& C_{4}=\left[\begin{array}{cccc}
1 & - & - & 1 \\
- & 1 & 1 & - \\
- & 1 & 1 & - \\
1 & - & - & 1
\end{array}\right]
\end{aligned}
$$

After superimposing the signs of entries of $C_{1}, C_{2}, C_{3}$ and $C_{4}$ over on the blocks of the matrices $L_{1}, L_{2}, L_{1}$ and $L_{2}$ respectively we get the matrix $H$ below:

$$
\begin{gathered}
K_{1}=C_{1} * L_{1}=\left[\begin{array}{llll}
A_{1} & A_{2} & A_{3} & A_{4} \\
A_{4} & A_{1} & A_{2} & A_{3} \\
A_{3} & A_{4} & A_{1} & A_{2} \\
A_{2} & A_{3} & A_{4} & A_{1}
\end{array}\right] \\
K_{2}=C_{2} * L_{2}=\left[\begin{array}{rrrr}
A_{1}^{t} & A_{2}^{t} & -A_{3}^{t} & -A_{4}^{t} \\
A_{4}^{t} & A_{1}^{t} & -A_{2}^{t} & -A_{3}^{t} \\
-A_{3}^{t} & -A_{4}^{t} & A_{1}^{t} & A_{2}^{t} \\
-A_{2}^{t} & -A_{3}^{t} & A_{4}^{t} & A_{1}^{t}
\end{array}\right] \\
K_{1}^{\prime}=C_{3} * L_{1}=\left[\begin{array}{rrrr}
A_{1} & -A_{2} & A_{3} & -A_{4} \\
-A_{4} & A_{1} & -A_{2} & A_{3} \\
A_{3} & -A_{4} & A_{1} & -A_{2} \\
-A_{2} & A_{3} & -A_{4} & A_{1}
\end{array}\right] \\
K_{2}^{\prime}=C_{4} * L_{2}=\left[\begin{array}{rrrr}
A_{1}^{t} & -A_{2}^{t} & -A_{3}^{t} & A_{4}^{t} \\
-A_{4}^{t} & A_{1}^{t} & A_{2}^{t} & -A_{3}^{t} \\
-A_{3}^{t} & A_{4}^{t} & A_{1}^{t} & -A_{2}^{t} \\
A_{2}^{t} & -A_{3}^{t} & -A_{4}^{t} & A_{1}^{t}
\end{array}\right] \\
H=\left[\begin{array}{rrrr}
K_{2} & K_{1}^{\prime} & K_{2}^{\prime} \\
K_{1} \\
K_{2} & K_{2}^{\prime} & K_{1}^{\prime} \\
-K_{1}^{\prime} & -K_{2}^{\prime} & K_{1} & K_{2} \\
-K_{2}^{\prime} & -K_{1}^{\prime} & K_{2} & K_{1}
\end{array}\right]=
\end{gathered}

## 4．3 A productive class of regular Hadamard matri－ ces

In this section we show that most of the regular Hadamard matrices constructed in section 2 are productive．We also need to mention some of the properties of a class of regular $\frac{1}{2}(m+1)$－set of matrices as given in［13］，whenever $m \equiv 3(\bmod 4)$ is a prime． Let $T$ be the circulant shift matrix of order $m$ defined by

$$
T=\left[t_{i j}\right] \text { where } t_{i j}= \begin{cases}1 & \text { if } i-j \equiv 1(\bmod \mathrm{~m})  \tag{4.1}\\ 0 & \text { otherwise }\end{cases}
$$

Let $R$ be the back－circulant shift matrix of order $m$ defined by

$$
R=\left[r_{i j} j \text { where } r_{i j}= \begin{cases}1 & \text { if } i+j \equiv 1(\bmod \mathrm{~m})  \tag{4.2}\\ 0 & \text { otherwise }\end{cases}\right.
$$

Then the following properties are immediate．

$$
\begin{gathered}
T^{m}=I,\left(T^{k}\right)^{t}=T^{m-k}, I+T+T^{2}+\cdots+T^{m-1}=J, R^{2}=I, \\
R T^{k}=R^{t} T^{k}=T^{m-k} R, J T^{k}=J R^{k}=J .
\end{gathered}
$$

Let $\chi$ be the so－called quadratic character on the field $G F(m)$ defined by

$$
\chi(x):=\left\{\begin{array}{lll}
0 & \text { if } & x=0 \\
1 & \text { if } & x \text { is a square } \\
-1 & \text { if } & x \text { is a non-square }
\end{array}\right.
$$

Let

$$
W=\left[w_{i j}\right] \text { where } w_{i j}=\chi(j-i), \text { for } i, j=0, \ldots, m-1
$$

By the definition it is clear that the matrix $W$ is a circulant matrix. Since $m \equiv 3(\bmod 4)$ we have $\chi(-1)=-1$ and $\chi(-x)=-\chi(x)$, thus the matrix $W$ is skew-symmetric ( $W^{t}=-W$ ). The following properties are immediate:

$$
W T=T W, W R=R^{t} W^{t}=R W^{t}=-R W
$$

Since the number of squares in $G F(m)$ is the same as the number of non-squares we have

$$
W J=0 .
$$

Also for any $0 \neq y \in G F(m)$ we have:

$$
\begin{aligned}
\sum_{x \in G F(m)} \chi(x) \chi(x+y) & =\sum_{x \in G F(m) \backslash 0} \chi(x) \chi(x) \chi\left(1+y x^{-1}\right) \\
& =\sum_{x \in G F(m) \backslash 0} \chi\left(1+y x^{-1}\right) \\
& =0-\chi(1) \\
& =-1
\end{aligned}
$$

So it follows that $W W^{t}=m I-J$. Let

$$
M:=I+W
$$

with top row $\left(b_{0}, b_{1}, \cdots, b_{m-1}\right)$. Then we have :

$$
\begin{equation*}
M M^{t}=(m+1) I-J, \quad M J=J \tag{4.3}
\end{equation*}
$$

Let $e=e_{m}=(1,1, \ldots, 1)$ be a vector of $m 1$ 's. Define the matrix

$$
\begin{aligned}
& N:=\epsilon^{t}\left(b_{0}, b_{1}, \cdots, b_{m-1}\right) \\
& =\left[\begin{array}{cccc}
b_{0} & b_{1} & \cdots & b_{m-1} \\
b_{0} & b_{1} & \cdots & b_{m-1} \\
\vdots & \vdots & \ddots & \vdots \\
b_{0} & b_{1} & \cdots & b_{m-1}
\end{array}\right]
\end{aligned}
$$

Using 4.3 since each of the rows of the matrix $N$ is the same as the first row of $M$ we have:

$$
N T^{k} N^{t}=\left\{\begin{array}{lll}
m J & \text { if } & k=0  \tag{4.4}\\
-J & \text { if } & 1 \leq k \leq m-1
\end{array}\right.
$$

The following useful properties are also obvious:

$$
N J=J, J N=m N, M N=T^{k} N=R^{k} N=N
$$

We now define the matrices $B_{j}$ and $C$ which play a key role in what follows:

$$
\begin{gather*}
B_{j}:=\sum_{i=0}^{m-1} R T^{i} \otimes M T^{i j}(j=1, \ldots, n-1)  \tag{4.5}\\
C:=N\left(I, T, T^{2}, \ldots, T^{m-1}\right)^{t} e=\left[\begin{array}{cccc}
N & N & \cdots & N \\
N T & N T & \cdots & N T \\
\vdots & \vdots & \ddots & \vdots \\
N T^{m-1} & N T^{m-1} & \cdots & N T^{m-1}
\end{array}\right] \tag{4.6}
\end{gather*}
$$

We will show that matrices $B_{i}$ and $C$ are an $(m+1) / 2$-set of matrices and that they also satisfy some additional properties that let us show that the matrix $H$, as defined in the previous section, is productive as well as regular. In order to show that the matrix $H$ is productive we should define a map that satisfies the properties of a productive regular Hadamard matrix. For convenience we define mappings on smaller blocks of the matrix $H$ step by step and then we introduce the final map using these maps.

Definition 4.4 Let $E$ be a $(1,-1)$ matrix of order $m^{2}$ and $I$ the identity matrix of order $m$. Define the map $\delta$ as follows:

$$
\delta E:=E(I \otimes T)
$$

As a consequence of the properties above, for all non-negative integers $\alpha$ :

1. $\delta^{\alpha} B_{j}=\delta\left(\delta^{\alpha-1} B_{j}\right)=B_{j}\left(I \otimes T^{\alpha}\right)=\sum_{i=0}^{m-1} R T^{i} \otimes M T^{i j+\alpha}$.
2. $\delta^{\alpha} C=C\left(I \otimes T^{\alpha}\right)=N T^{\alpha}\left(I, T, T^{2}, \ldots, T^{m-1}\right)^{t} e$.

Lemma 4.5 Let $\mathcal{F}=\left\{C, B_{1}, \cdots, B_{(m-1) / 2}\right\}$, and $\mathcal{G}=\left\{C, C^{t}, B_{1}, B_{1}^{t}, \cdots, B_{(m-1) / 2}, B_{(m-1) / 2}^{t}\right\}$. Then $\mathcal{F}, \mathcal{G}$ and $\delta$ satisfy the following conditions:
(i) $\delta^{m} X=X$ for all $X$ in $\mathcal{F}$;
(ii) $\left(\delta^{\alpha} X\right)(Y)^{t}=J$ for all $X \in \mathcal{F}, Y \in \mathcal{G}, X \neq Y$ and $\alpha \in\{0,1, \ldots, m-1\}$;
(iii) $\sum_{i=0}^{m-1} \delta^{i} X=J$ for all $X \in \mathcal{F}$;
(iv) $(\delta X)(\delta Y)^{t}=X Y^{t}$ for every matrices $X, Y$ of order $m^{2}$.

Proof The proof of condition (i) follows from the fact that $T^{m}=I$.
To prove condition (ii) we have to consider the following sub-cases.
For all positive integers $j, k$ not exceeding $(m-1) / 2$ :
(iii $)\left(\delta^{\alpha} B_{j}\right)\left(B_{k}^{t}\right)^{t}=J$;
(iii ) $\left(\delta^{\alpha} B_{j}\right)\left(B_{k}\right)^{t}=J$ if $(j \neq k)$;
(ii $\left.{ }_{3}\right)\left(\delta^{\alpha} B_{k}\right)\left(C^{t}\right)^{t}=J ;$
(iii $)\left(\delta^{\alpha} C\right)\left(B_{k}^{t}\right)^{t}=J$;
(ii $\left.{ }_{5}\right)\left(\delta^{\alpha} C\right)\left(B_{k}\right)^{t}=J$;
(ii $\left.{ }_{6}\right)\left(\delta^{\alpha} C\right)\left(C^{t}\right)^{t}=J$.
The proofs of these properties parallel proofs given in [13].
(ii ${ }_{1}$ )

$$
\begin{aligned}
\left(\delta^{\alpha} B_{j}\right)\left(B_{k}\right) & =\sum_{i=0}^{m-1} \sum_{h=0}^{m-1} R T^{i} R T^{h} \otimes M T^{i j+\alpha} M T^{h k} \\
& =\sum_{h=0}^{m-1} \sum_{i=0}^{m-1} T^{m+h-i} \otimes M^{2} T^{i j+h k+\alpha} \\
& =\sum_{z=0}^{m-1} \sum_{i=0}^{m-1} T^{z} \otimes M^{2} T^{i(j+k)+z k+\alpha} \quad(\text { where } z=h-i) \\
& =\sum_{z=0}^{m-1} T^{z} \otimes M^{2} J \\
& =J \otimes J .
\end{aligned}
$$

Note that $j+k \neq m$ since $j, k \leq(m-1) / 2$.
(ii ${ }_{2}$ )

$$
\begin{aligned}
\left(\delta^{\alpha} B_{j}\right)\left(B_{k}\right)^{t} & =\sum_{i=0}^{n-1} \sum_{h=0}^{n-1} R T^{i}\left(R T^{h}\right)^{t} \otimes M T^{i j+\alpha}\left(M T^{h k}\right)^{t} \\
& =\sum_{i=0}^{n-1} \sum_{h=0}^{n-1} T^{h-i} \otimes M M^{t} T^{i j-h k+\alpha} \\
& =\sum_{z=0}^{n-1} \sum_{h=0}^{n-1} T^{z} \otimes M M^{t} T^{i(j-k)-z k+\alpha} \quad(\text { where } z=h-i) \\
& =\sum_{z=0}^{n-1} T^{z} \otimes J \\
& =J \otimes J .
\end{aligned}
$$

(iii3)

$$
\begin{aligned}
{\left[\left(\delta^{\alpha} B_{k}\right)(C)\right]_{i j} } & =\sum_{h=0}^{m-1} T^{(i+h) k}\left(M T^{\alpha}\right) N T^{h} \\
& =M N \sum_{h=0}^{m-1} T^{h} \\
& =M N J=J .
\end{aligned}
$$

(ii4)

$$
\begin{aligned}
\left(\left(\delta^{\alpha} C\right)\left(B_{k}\right)!_{i j}\right. & =\left(N T^{\alpha}\right) T^{i} M \sum_{h=0}^{n-1} T^{(j+h) k} \\
& =N T^{i+\alpha} M J \\
& =N T^{i+\alpha} J \\
& =N J=J
\end{aligned}
$$

(ii ${ }_{5}$ )

$$
\begin{aligned}
{\left[\left(\delta^{\alpha} C\right)\left(B_{k}\right)^{t}\right]_{i j} } & =\sum_{h=0}^{n-1}\left(\delta^{\alpha} C\right)_{i h}\left(B_{k}\right)_{h j}^{t} \\
& =\sum_{h=0}^{n-1}\left(N T^{\alpha}\right) T^{i}\left(T^{(h+j) k} M\right)^{t} \\
& =\sum_{h=0}^{n-1} N T^{\alpha+i} T^{n-(h+j) k} M^{t} \\
& =N M^{t} \sum_{h=0}^{n-1} T^{\alpha+i-(h+j) k} \\
& =N M^{t} J \\
& =N J=J .
\end{aligned}
$$

(ii6)

$$
\begin{aligned}
\left(\left(\delta^{\alpha} C\right)(C)\right]_{i j} & =\left(N T^{\alpha}\right) T^{i} N \sum_{h=0}^{m-1} T^{h} \\
& =N T^{i+\alpha} N J \\
& =N N J=J .
\end{aligned}
$$

To prove condition (iii) we have:

$$
\begin{aligned}
\sum_{\alpha=0}^{m-1} \delta^{\alpha} B_{i} & =\sum_{\alpha=0}^{m-1} \sum_{i=0}^{m-1} R T^{i} \otimes M T^{i j+\alpha} \\
& =\sum_{i=0}^{m-1} R T^{i} \otimes\left(\sum_{\alpha=0}^{m-1} M T^{i j+\alpha}\right) \\
& =\sum_{i=0}^{m-1} R T^{i} \otimes(M J) \\
& =J \otimes J
\end{aligned}
$$

Also

$$
\begin{aligned}
\sum_{\alpha=0}^{m-1} \delta^{\alpha} C & =\sum_{\alpha=0}^{m-1}\left(N T^{\alpha}\right)\left(I, T, T^{2}, \ldots, T^{m-1}\right)^{t} e \\
& =(N J)\left(I, T, T^{2}, \ldots, T^{m-1}\right)^{t} e \\
& =J\left(I, T, T^{2}, \ldots, T^{m-1}\right)^{t} e \\
& =J \otimes J .
\end{aligned}
$$

To prove condition (iv) we have :

$$
\begin{aligned}
(\delta X)(\delta Y)^{t} & =(X(I \otimes T))(Y(I \otimes T))^{t} \\
& =X(I \otimes T)\left(I \otimes T^{n-1}\right) Y^{t} \\
& =X(I \otimes I) Y^{t} \\
& =X Y^{t} .
\end{aligned}
$$

To prove that matrices $B_{i}$ and $C$ defined above form a regular $s$-set using Lemma 4.5 part (ii) it is sufficient to prove the next lemma

## Lemma 4.6

$$
\sum_{i=1}^{(m-1) / 2}\left(B_{i} B_{i}^{t}+B_{i}^{t} B_{i}\right)+C C^{t}+C^{t} C=n^{2}(n+1) I
$$

Proof

$$
\begin{aligned}
{\left[C C^{t}\right]_{i j} } & =m N T^{i} T^{m-i} N^{t} \\
& =m N T^{i-j} N^{t} \\
& = \begin{cases}m^{2} J & \text { if } i=j \\
-m J & \text { otherwise. }\end{cases}
\end{aligned}
$$

So

$$
\begin{equation*}
C C^{t}=m(m+1) I \otimes J-m J \otimes J \tag{4.7}
\end{equation*}
$$

We know that each row of matrix $N$ is the vector $\left(b_{0}, b_{1}, \cdots, b_{m-1}\right)$, where $b_{0}=1$ and $b_{i}=\chi(i)$ so we have:

$$
\left[\sum_{k=0}^{m-1} T^{k}\left(N^{t} N\right) T^{-k}\right]_{i j}=m \sum_{k=0}^{m-1} b_{i+k} b_{j+k}
$$

If $i=j$ :

$$
\left[\sum_{k=0}^{m-1} T^{k}\left(N^{t} N\right) T^{-k} \bar{j}_{j i}=m \sum_{k=0}^{m-1} b_{i+k}^{2}=m^{2} .\right.
$$

If $i \neq j$ :

$$
\left[\sum_{k=0}^{m-1} T^{k}\left(N^{t} N\right) T^{-k}\right]_{i j}=m\left(b_{0} b_{j-1}+b_{i-j} b_{0}\right)+m \sum_{k=0}^{m-1} \chi(i+k) \chi(j+k)=-m
$$

So

$$
\sum_{k=0}^{m-1} T^{k}\left(N^{t} N\right) T^{-k}=m(m+1) I-m J
$$

Now we are able to calculate $C^{t} C$.

$$
\begin{align*}
C^{t} C & =J \otimes \sum_{k=0}^{m-1}\left(N T^{k}\right)^{t}\left(N T^{k}\right) \\
& =J \otimes \sum_{k=0}^{m-1} T^{-k}\left(N^{t} N\right) T^{k} \\
& =J \otimes \sum_{k=0}^{m-1} T^{k}\left(N^{t} N\right) T^{-k} \\
& =m J \otimes((m+1) I-J) \tag{4.8}
\end{align*}
$$

To calculate $B_{j} B_{j}^{t}$ and $B_{j}^{t} B_{j}$ as well we have:

$$
\begin{aligned}
B_{j} B_{j}^{t} & =\sum_{i=1}^{m-1} \sum_{h=0}^{m-1} R T^{i}\left(R T^{h}\right)^{h} \otimes M T^{i j}\left(M T^{h j}\right)^{t} \\
& =\sum_{i=0}^{m-1} \sum_{h=0}^{m-1} T^{h-i} \otimes M M^{t} T^{i j-h j} \\
& =\sum_{z=0}^{m-1} \sum_{i=0}^{m-1} T^{z} \otimes M M^{t} T^{-z j} \quad(z=h-i) \\
& =m \sum_{z=0}^{m-1} T^{z} \otimes M M^{t} T^{-z j}
\end{aligned}
$$

Similarly one can show that:

$$
B_{j}^{t} B_{j}=m \sum_{z=0}^{m-1} T^{z} \otimes M M^{t} T^{z j}
$$

Now we have:

$$
\begin{align*}
\sum_{i=1}^{(m-1) / 2}\left(B_{i} B_{i}^{t}+B_{i}^{t} B_{i}\right)= & m \sum_{z=0}^{m-1} \sum_{i=1}^{(m-1) / 2} T^{z} \otimes M M^{t} T^{-z i}+m \sum_{z=0}^{m-1} \sum_{i=1}^{(m-1) / 2} T^{z} \otimes M M^{t} T^{z i} \\
= & m \sum_{z=0}^{m-1} \sum_{j=1}^{m-1} T^{z} \otimes M M^{t} T^{-z j} \\
= & m\left(I \otimes(m-1) M M^{t}+\sum_{z=1}^{m-1} T^{z} \otimes M M^{t}(J-I)\right) \\
= & I \otimes m(m-1) M M^{t}+(J-I) \otimes m M M^{t}(J-I) \\
= & \left(I \otimes M M^{t}\right)\left(m^{2} I \otimes I-m I \otimes J-m J \otimes I+m(J \otimes J)\right) \\
= & m^{2}(m+1) I \otimes I-m(m+1) J \otimes I \\
& -m(m+1) I \otimes J+2 m J \otimes J \tag{4.9}
\end{align*}
$$

Using 4.7, 4.8, and 4.9 the result follows
Lemma 4.7 There is a permutation matrix $P_{i}$ such that $C_{i} P_{i}=-C_{i}, P_{i}^{2}=I$ for all $2 \leq i \leq 4 n$.

Proof Noting that $C_{i}=r_{i}^{t} r_{i}$, as defined in section 4.2, where $r_{i}$ is any row of a normalised Hadamard matrix of order $4 n$. Since $r_{i} r_{1}^{t}=0$ there are exactly $2 n$ ones in $r_{i}$. Let $\tau_{1}$ be any permutation that moves the +1 's of $r_{i}$ to the left and -1 's to the right. Thus

$$
\tau_{1} r_{i}=11 \cdots 1--\cdots-
$$

Let $\tau_{2}=(12 n+1)(22 n+2) \cdots(2 n 4 n)$. We have $\tau_{2} \tau_{1} r_{i}=-\tau_{1} r_{i}$. So $\tau_{1}^{-1} \tau_{2} \tau_{1} r_{i}=-r_{i}$. Let $\tau=\tau_{1}^{-1} \tau_{2} \tau_{1}$, we have $\tau r_{i}=-r_{i}$. The matrix $P_{i}$ of the permutation $\tau$ is the required permutation matrix, $r_{i}^{t} r_{i} P_{i}=-r_{i}^{t} r_{i}$ and $P_{i}^{2}=I$.

Let

$$
V:=P_{2 n+1} \otimes I_{m^{2}}
$$

then $V^{2}=I$ and $V^{t}=V$.
Definition 4.8 Let $E$ be a $(1,-1)$ matrix of order $4 n m^{2}$ and $I$ the identity matrix of order 4 nm . Define the map $\rho$ as follows:

$$
\rho E:=E(I \otimes T) V
$$

Lemma 4.9 Let $\mathcal{R}=\left\{K_{1}, K_{1}^{\prime}\right\}$ and $\mathcal{S}=\left\{K_{2}, \cdots, K_{2 n}, K_{2}^{\prime}, \cdots, K_{2 n}^{\prime}\right\}$, where $K_{i}$ 's are matrices of order $4 n^{2}$ as defined on page 47. Then $\mathcal{S}, \mathcal{R}$, and $\rho$ satisfy the following properties:
(i) $\rho^{2 m} X=I$ for every matrix $X$ of size $2 n m^{2}$;
(ii) $\left(\rho^{\alpha} X\right)(Y)^{t}=0$ for all $X \in \mathcal{R}, Y \in \mathcal{S}, \alpha=0, \cdots: 2 m-1$;
(iii) $(\rho X)(\rho Y)^{t}=X Y^{t}$ for all matrices $X$, and $Y$ of size $4 n m^{2}$;
(iv) $\sum_{i=0}^{2 m-1} \rho^{i} K_{1}=2 J$ and $\sum_{i=0}^{2 m-1} \rho^{i} K_{1}^{\prime}=0$.

Proof It is easy to see the validity of properties (i) and (iii). The proof of (ii) is an immediate consequence of Lemma 4.5 and properties of $K_{i} \mathrm{~s}$ and $K_{i}^{\prime} \mathrm{s}$.
To prove (iv), we use Lemma 4.5 part (iii) to get

$$
\sum_{i=0}^{m-1} L_{1}\left(I \otimes T^{i}\right)=J \otimes J
$$

Now we have:

$$
\begin{aligned}
\sum_{i=0}^{2 m-1} \rho^{i} K_{1} & =\sum_{i=0}^{m-1} L_{1}\left(I \otimes T^{i}\right)+\sum_{i=0}^{m-1} L_{1}\left(I \otimes T^{i}\right) V \\
& =J \otimes J+(J \otimes J) V \\
& =2 J \otimes J
\end{aligned}
$$

$$
\begin{aligned}
\sum_{i=0}^{2 m-1} \rho^{i} K_{1}^{\prime} & =\sum_{i=0}^{m-1} C_{2 n+1} * L_{1}\left(I \otimes T^{i}\right)+\sum_{i=0}^{m-1} C_{2 n+1} * L_{1}\left(I \otimes T^{i}\right) V \\
& =C_{2 n+1} *(J \otimes J)+C_{2 n-1} *(J \otimes J) V \\
& =C_{2 n+1} \otimes J+\left(C_{2 n+1} \otimes J\right) V \\
& =C_{2 n+1} \otimes J+\left(C_{2 n+1} \otimes J\right)\left(P_{2 n+1} \otimes I\right) \\
& =C_{2 n+1} \otimes J+\left(C_{2 n+1} P_{2 n+1}\right) \otimes J \\
& =C_{2 n+1} \otimes J-C_{2 n-1} \otimes J=0
\end{aligned}
$$

Following a notation of Ionin [5], we let $\mathcal{M}$ be the set of block matrices $D=\left[D_{i j} j, i, j=\right.$ $1, \ldots, 4 n$, such that:
(i) for each $i=1, \cdots, 4 n$, there is a unique $h_{i}=h_{i}(D) \in\{1, \cdots, 4 n\}$, such that for $j=h_{i}, D_{i j}=\rho^{\alpha} K_{1}$ for some integer $\alpha$;
(ii) for each $i, i=1, \cdots, 4 n$, there is a unique $h_{i}^{\prime}=h_{i}^{\prime}(D) \in\{1, \cdots, 4 n\}, h_{i}^{\prime} \neq h_{i}$ such that for $j=h_{i}^{\prime}, D_{i j}= \pm \rho^{\alpha} K_{1}^{\prime}$ for some integer $\alpha$;
(iii) for $i=1, \cdots, 4 n$, and for $j \neq h_{i}$ and $j \neq h_{i}^{\prime}, D_{i j}= \pm K_{l}$ or $\pm K_{l}^{\prime}$ for $l=2, \cdots, 2 n$.

Clearly $H$ is an element of $\mathcal{M}$. Define a bijection $\sigma: \mathcal{M} \rightarrow \mathcal{M}$ by $\sigma D=D^{\prime}=\left\{D_{i j}^{\prime}\right\}$ where:
(i) for $i=1, \ldots, 4 n$, and $j=2, \ldots, 4 n, D_{i j}^{\prime}=D_{i, j-1}$;
(ii) for $i=1, \ldots, 4 n$, if $h_{i}(D)=4 n$ or $h_{i}^{\prime}(D)=4 n$ then $D_{i 1}^{\prime}=\rho D_{i, 4 n}$;
(iii) for $i=1, \ldots, 4 n$, if $h_{i}(D) \neq 4 n$ and $h_{i}^{\prime}(D) \neq 4 n$ then $D_{i 1}^{\prime}=-D_{i, 4 n}$.

It follows from the fact that $\rho^{2 m}=1$ and from the number of blocks of $D$ that the order of the cyclic group $G$ generated by $\sigma$ is 8 nm .

Lemma 4.10 For $X, Y \in \mathcal{M},(\sigma X)(\sigma Y)^{t}=X Y^{t}$.
Proof Let $X, Y \in \mathcal{M}$ and let $X^{\prime}=\sigma X$ and $Y^{\prime}=\sigma Y$. It is sufficient to show that, for $i, i^{\prime}=1, \ldots, 4 n$,

$$
X_{i 1}^{\prime} Y_{i^{\prime} 1}^{t}=X_{i, 4 n} Y_{i^{\prime}, 4 n}^{t}
$$

Let $\mathcal{R}^{\prime}=\left\{\rho^{\alpha} K_{1}, \pm \rho^{\alpha} K_{1}^{\prime} \mid \alpha=0, \cdots, 2 m-1\right\}$ and let $\mathcal{S}^{\prime}=\left\{ \pm K_{l}, \pm K_{l}^{\prime} \mid l=2, \cdots, 2 n\right\}$. It is obvious that $X_{i, 4 n}$ and $Y_{i^{\prime}, 4 n}$ are either in $\mathcal{R}^{\prime}$ or in $\mathcal{S}^{\prime}$. We have to check the following cases:

- If $X_{i, 4 n} \in \mathcal{S}^{\prime}$ and $Y_{i^{\prime}, 4 n} \in \mathcal{S}^{\prime}$ then $X_{i 1}^{\prime} Y_{i^{\prime} 1}^{\prime t}=\left(-X_{i, 4 n}\right)\left(-Y_{i^{\prime}, 4 n}\right)^{t}=X_{i, 4 n} Y_{i^{\prime}, 4 n}^{t}$.
- If $X_{i, 4 n} \in \mathcal{R}^{\prime}$ and $Y_{i^{\prime}, 4 n} \in \mathcal{S}^{\prime}$ then using Lemma 4.9 we can see that $X_{i 1}^{\prime} Y_{i^{\prime} 1}^{\prime t}=$ $X_{i, 4 n} Y_{i^{\prime}, 4 n}^{t}=0$.
- The proof for the case $X_{i, 4 n} \in \mathcal{S}^{\prime}$ and $Y_{i^{\prime}, 4 n} \in \mathcal{R}^{\prime}$ is similar and we omit it.
- If $X_{i, 4 n} \in \mathcal{R}^{\prime}$ and $Y_{i^{\prime}, 4 n} \in \mathcal{R}^{\prime}$ then $X_{i 1}^{\prime} Y_{i^{\prime} 1}^{\prime t}=\left(\rho X_{i, 4 n}\right)\left(\rho Y_{i^{\prime}, 4 n}\right)^{t}=X_{i, 4 n} Y_{i^{\prime}, 4 n}^{t}$.

Lemma $4.11 \sum_{g=0}^{8 n m-1} \sigma^{g} H=2 J$.
Proof Using Lemma 4.9, if $1 \leq i \leq 2 n$ we see that the ( $i, j$ )-block of the matrix $\sum_{g=1}^{8 n m} \sigma^{g} H$ is:

$$
\begin{aligned}
{\left[\sum_{l=0}^{8 n m-1} \sigma^{l} H\right]_{i j} } & =\sum_{\alpha=0}^{2 m-1} \rho^{\alpha} K_{1}-\sum_{\alpha=0}^{2 m-1} \rho^{\alpha} K_{1}^{\prime} \\
& =2 J+0=2 J .
\end{aligned}
$$

If $2 n<i \leq 4 n$ we have:

$$
\begin{aligned}
\left.\sum_{l=0}^{8 n m-1} \sigma^{l} H\right]_{i j} & =\sum_{\alpha=0}^{2 m-1} \rho^{\alpha} K_{1}-\sum_{\alpha=0}^{2 m-1} \rho^{\alpha} K_{1}^{\prime} \\
& =2 J-0=2 J .
\end{aligned}
$$

Theorem 4.12 The matrix $H$ is productive.
Proof Using lemmas 4.10 and 4.11 we see that the matrix $H$, the set $\mathcal{M}$ and the bijection $\sigma$ satisfy all of the conditions of definition 3.4.

We are now ready to apply a recent result of Ionin [4] to construct many new classes of symmetric designs. We start with a definition.

Let $m=8 n^{2}-1$ be a prime number. Then the matrix $H$ above, and consequently the matrix $-H$, has a group of symmetry. Let $G$ be the group of symmetry defined above. Upon Theorem 3.6, we get the following corollary.

Corollary 4.13 Let $m=8 n^{2}-1$ be a prime number.

- If $q=(4 n m-1)^{2}$ is a prime power, then there is a symmetric design with parameters

$$
\left(16 n^{2} m^{2}\left(q^{t}+q^{t-1}+\ldots+1\right),\left(8 n^{2} m^{2}-2 n m\right) q^{t},\left(4 n^{2} m^{2}-2 n m\right) q^{t}\right)
$$

for every nonnegative integer $t$.

- If $q=(4 n m+1)^{2}$ is a prime power then there is a symmetric design with parameters

$$
\left(16 n^{2} m^{2}\left(q^{t}+q^{t-1}+\ldots+1\right),\left(8 n^{2} m^{2}+2 n m\right) q^{t},\left(4 n^{2} m^{2}+2 n m\right) q^{t}\right)
$$

for every nonnegative integer $t$.
Remark 4.14 We need to close the thesis with an explanation to link our work in different chapters of this document. Our original aim was to use the $T$-matrices introduced in chapter 2 to generate a productive class of regular Hadamard matrices. Soon after we were convinced that this was a very tough project requiring longer time. We then turned our attention to Mathon matrices and Kharaghani matrices and our search was successful. We end this thesis with high hopes of getting an opportunity to spend more time on techniques akin to Xia and Xia and developing it into another productive class of regular Hadamard matrices.
