Received 16 August 2012; accepted 31 August 2012

Key indicators: single-crystal X-ray study;  $T = 173$  K; mean  $\sigma(C-C) = 0.002$  Å; disorder in main residue;  $R$  factor = 0.039;  $wR$  factor = 0.101; data-to-parameter ratio = 20.3.

In the title compound,  $C_{16}H_{26}NO^+\cdot Cl^- \cdot 0.5H_2O$ , the asymmetric unit consists of two independent cations, their respective chloride anions and a solvent water molecule. Together they form a discrete crescent-shaped entity linked by hydrogen bonds from the central water atom to two  $Cl^-$  ions and from the latter to two protonated imine groups. The geometries of the two independent cations are essentially the same. The planar  $N=C(O)CH_3$  groups in each (r.m.s. deviations = 0.0011 and 0.0026 Å) form dihedral angles of 75.28 (5) and 79.10 (4)° with the benzene rings. In one cation, the methyl atoms of one of the isopropyl groups were modeled as disordered over two sets of sites, with refined occupancies of 0.589 (17) and 0.411 (17).

## (Z)-N-(1-Ethoxyethylidene)-2,6-bis(propan-2-yl)anilinium chloride hemihydrate

Leila Mokhtabad Amrei and René T. Boeré

### S1. Comment

The structure of the two independent cations in (I) is shown in Fig. 1. In one cation (*b*) the isopropyl group was refined with a two component disorder model (C31,C32, C31A & C32A). In the structure of 5-(2-((1-ethoxyethylidene)ammonio)-2-methylpropyl)thianthrenium diperchlorate (II) (Shine *et al.*, 2004), which is the only other compound with an ethoxyiminium group that we could locate in the Cambridge Structural Database (Allen, 2002; WebCSD June 2012) (refcode: FARCAD), the geometry about the iminium bond is also Z.

The H-bonded cluster, shown in Fig. 2, is the asymmetric unit in the crystal. Both imino nitrogen atoms N1 and N2 are protonated and form strong hydrogen bonds (Table 1) with their respective chloride anions Cl1 and Cl2, within the s.u. of the expected N···Cl distance of 3.19 (7) Å (Fuller, 1959) but clearly on the short end of this scale. The N1···Cl1 bond is comparable in strength to that between N1 and Cl1 in the crystal structure of 2,6-di-isopropyl-N-((1-(2-methylprop-2-en-1-yl)cyclohexyl)methylidene)anilinium chloride chloroform solvate (III) (Refcode: GIBLAF) at 3.077 (4) Å (Jazzar *et al.*, 2007); and shorter than N1···Br1 in 2-((2,6-diisopropylphenyl)iminio)propyl bromide (IV), (Refcode: OJIKX) at 3.196 (1) Å (Zhang *et al.*, 2003). There are additional hydrogen bonds in structure (I) between the two water hydrogen atoms and the chloride anions (Table 1 & Figure 2).

The iminium bond lengths N1=C13, 1.2956 (18) Å and N2=C33, 1.2945 (18) Å, fit well with standard values for C=N of 1.287 (21) Å, whereas the standard value for C—N is 1.479 (36) Å, (Orpen *et al.*, 1989). Comparative N=C values occur in structures (II), 1.289 (5), (III), 1.289 (4) and (IV), 1.290 (2) Å. In (I), the O1—C13 bond length is 1.3068 (17) Å and O2—C33 is 1.3062 (17) Å, indicative of partial double bonds (standard bond lengths for C—O are 1.43 (1) Å, for C=O, 1.23 (1) Å, and for Csp<sup>2</sup>=O, 1.354 (16) Å (Allen *et al.*, 1987)).

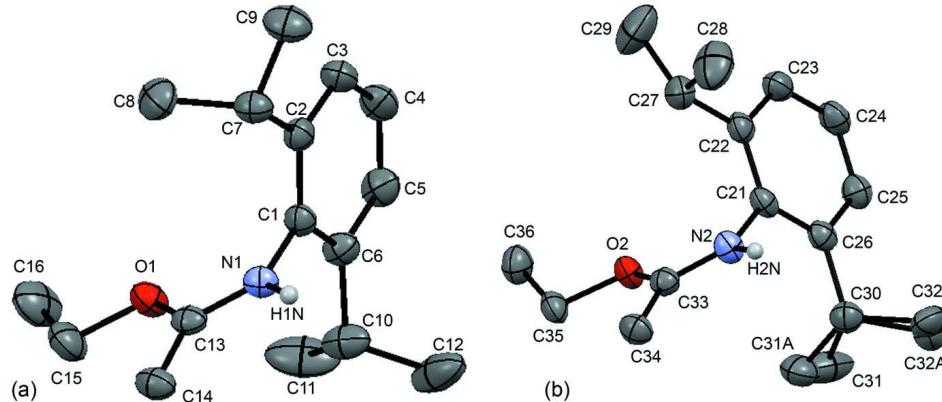

### S2. Experimental

The title compound (I) was obtained as a side product of the reaction of (2,6-diisopropylphenyl)phosphine with *N*-[2,6-bis(1-methylethyl)phenyl]-2,2-dimethylmethanimidoyl chloride (Boeré *et al.*, 1998) in THF solution (24 h reflux). While the main product precipitated after cooling, the filtrate was evaporated and treated with ethanol. On cooling this mixture to 243 K for an extended period, crystals of (I) formed as colourless blocks. Presumably, (I) forms by the direct nucleophilic addition of ethanol to unreacted imidoyl chloride. It crystallizes as a hemi-hydrate.

### S3. Refinement

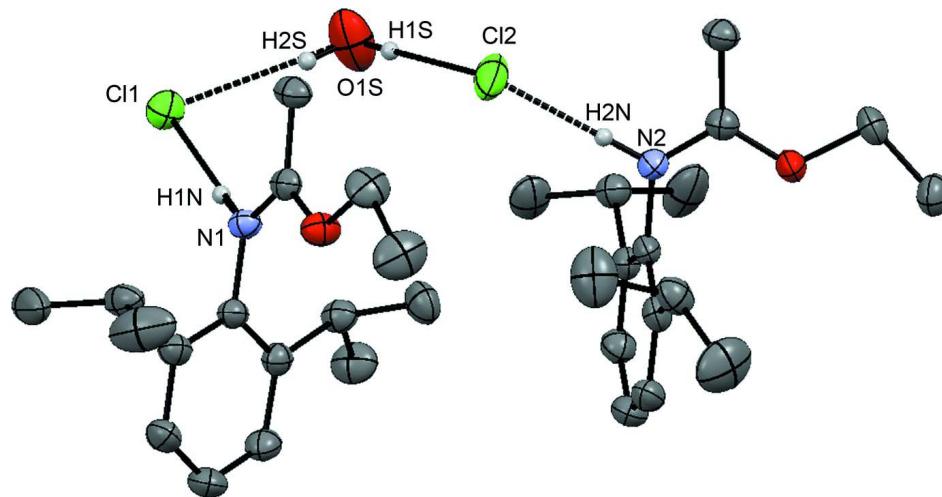

During refinement, the methyl groups of one isopropyl group on each of the cations, specifically C8 & C9 and C31 & C32, evidenced large anisotropic displacements. Attempts to define a two-position disorder model for C8 & C9 failed, so these atoms have been treated by a straightforward anisotropic refinement. However, a very reasonable chemical model ensued from a two-position disorder model for C31 and C32 (refined occupancy ratio of 0.589 (17):0.411 (17)). Attempts to include C30 within the disorder model did not lead to a stable refinement, so the second methine carbon was

geometrically defined by a dummy atom to ensure the generation of the disordered H atoms on this atom. Hydrogen atoms attached to carbon were treated as riding, with C—H = 0.98 Å and  $U_{\text{iso}}(\text{H}) = 1.5U_{\text{eq}}(\text{C})$  for methyl, C—H = 1.00 Å and  $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$  for methine and C—H = 0.95 Å and  $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$  for aromatic H atoms. The NH and OH hydrogen positions are freely refined with isotropic displacements.

**Figure 1**

The two independent cations of the title compound with ellipsoids drawn at the 50% probability level. H atoms bonded to C atoms are not shown. Atoms labeled C31/C32/C31A/C32A are the components of disorder.

**Figure 2**

The asymmetric unit of the title compound showing hydrogen bonds as dashed lines. Displacement ellipsoids are drawn at 30% probability level. Neither the disorder nor H atoms bonded to C atoms are shown.

 $\Delta\rho_{\max} = 0.26 \text{ e \AA}^{-3}$   
 $\Delta\rho_{\min} = -0.37 \text{ e \AA}^{-3}$

#### Special details

**Experimental.** A crystal coated in Paratone (TM) oil was mounted on the end of a thin glass capillary and cooled in the gas stream of the diffractometer Kryoflex device.

**Geometry.** All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted  $R$ -factor  $wR$  and goodness of fit  $S$  are based on  $F^2$ , conventional  $R$ -factors  $R$  are based on  $F$ , with  $F$  set to zero for negative  $F^2$ . The threshold expression of  $F^2 > \sigma(F^2)$  is used only for calculating  $R$ -factors(gt) etc. and is not relevant to the choice of reflections for refinement.  $R$ -factors based on  $F^2$  are statistically about twice as large as those based on  $F$ , and  $R$ -factors based on ALL data will be even larger.
