## Abstract

The  $[\text{SF}_4 \cdot \text{O}=\text{C}(\text{CH}_3)_2]_2$  and  $\text{SF}_4 \cdot [\text{O}=\text{C}(\text{CH}_3)_2]_2$  adducts were synthesized and characterized at low temperature (LT) using Raman spectroscopy and, in the case of  $[\text{SF}_4 \cdot \text{O}=\text{C}(\text{CH}_3)_2]_2$ , single-crystal X-ray diffraction. The X-ray crystal structure of  $\text{SF}_4 \cdot (\text{O}=\text{C}_{10}\text{H}_{14}) \cdot (\text{HF})$  was obtained, showing  $\text{F}_4\text{S} \cdots \text{F}-\text{H} \cdots \text{O}=\text{C}_{10}\text{H}_{14}$  interactions.

Adducts of  $[\text{SF}_3]^+$  with acetone, cyclopentanone, and 2-adamantanone were shown by  $^{19}\text{F}$  and  $^1\text{H}$  NMR spectroscopy to exist in solutions below  $-40^\circ\text{C}$ . The proposed  $[\text{SF}_3 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_3]^+$  cation was observed at LT by reacting  $[\text{SF}_3][\text{AsF}_6]$  with excess acetone. Above  $-40^\circ\text{C}$   $\text{SF}_4$  formation was observed.

Protonated ketones,  $[\text{HO}=\text{R}]^+$  ( $\text{R} = \text{C}(\text{CH}_3)_2$ ,  $\text{C}_5\text{H}_8$ ,  $\text{C}_{10}\text{H}_{14}$ ), and aldehydes,  $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2]^+$  and  $[\text{H}(\text{O}=\text{CHCH}_3)_x]^+$  ( $x = 1$  or  $2$ ), were isolated and characterized in the solid state for the first time. NBO analyses were used to quantify the increase in electrophilicity of the oxonium cations.

The  $\text{AsF}_5 \cdot \text{O}=\text{R}$  ( $\text{R} = \text{C}(\text{CH}_3)_2$ ,  $\text{C}_5\text{H}_8$ ,  $\text{C}_{10}\text{H}_{14}$ ) adducts were synthesized and characterized in solution and solid state using LT NMR and Raman spectroscopies, respectively.

## **Acknowledgments**

I would like to thank my supervisor, Dr. Michael Gerken, for his mentorship during my time in his research group. His patience, enthusiasm, and immense knowledge in the field of fluorine chemistry make him an excellent supervisor and inspired me to become a better chemist. Thank you for providing me with the opportunity to work in your lab.

I would like to thank my committee members, Dr. Peter Dibble and Dr. Paul Hazendonk, for their encouragement and insightful comments over the course of my graduate studies.

I would like to thank Dr. Jens Müller for taking time out of his busy schedule to review my thesis and travel to Lethbridge for my defence.

Sincere thank-you goes out to Dr. Stacey D. Wetmore for providing me with the computational resources throughout this thesis, as well as her guidance during the preparation and submission of our published manuscript. I would also like to thank Dr. René T. Boéré for doing an excellent job in teaching me the basics of X-ray crystallography during his course.

Thank you to the members of the Gerken group, Nathan Kostiuk and Douglas Turnbull, for their friendship, assistance in the lab, and many entertaining conversations. A special thanks to Nathan for helping settle into Lethbridge and introducing me to many new friends. I am also thankful for my fellow graduate student peers, Connor and Jackson, for all the amazing days skiing in the mountains.

A heartfelt thanks to all the friends I made throughout the past few years, especially Kathleen, Katelyn, and Chris who have made my time in Lethbridge extra special.

Finally, I would like to thank my family for their endless encouragement, constant love, and support. I am especially thankful for my parents, Pat and Mike, who are the reason I am where I am today. You are always there for me and I am eternally grateful.

## Table of Contents

<b>1. Introduction.....</b>	<b>1</b>
1.1 Organofluorine Chemistry .....	1
1.1.1 Deoxofluorination Reactions .....	4
1.2 Sulfur Tetrafluoride .....	13
1.2.1 Adducts of SF <sub>4</sub> and Organic Nitrogen and Oxygen Bases .....	14
1.3 The Chemistry of [SF <sub>3</sub> ] <sup>+</sup> .....	17
1.3.1 [SF <sub>3</sub> ] <sup>+</sup> ·Nitrogen-Base Adducts.....	19
1.4 Goals of Present Research .....	21
<b>2. Experimental .....</b>	<b>27</b>
2.1 General Methods .....	27
2.2 Preparation and Purification of Starting Materials .....	31
2.2.1 Sources and Purification of N <sub>2</sub> and F <sub>2</sub> .....	31
2.2.2 Solvent Purification; Anhydrous HF (aHF), SO <sub>2</sub> , CH <sub>2</sub> Cl <sub>2</sub> , and CFCl <sub>3</sub> .....	32
2.2.3 Purification of Oxygen-Bases .....	34
2.2.4 Synthesis and Purification of SF <sub>4</sub> , SbF <sub>3</sub> and AsF <sub>5</sub> .....	34
2.2.5 Synthesis of [SF <sub>3</sub> ][AsF <sub>6</sub> ].....	35
2.3 Reactions of SF <sub>4</sub> with Ketones .....	35
2.3.1 Reaction of SF <sub>4</sub> with 2-Adamantanone.....	35
2.3.2 Reactions of SF <sub>4</sub> with Acetone .....	36
2.3.2.1 Reactions of SF <sub>4</sub> with One Equivalent of Acetone .....	36
2.3.2.2 Reactions of SF <sub>4</sub> with Two Equivalents of Acetone .....	37
2.4 Reactions of [SF <sub>3</sub> ][AsF <sub>6</sub> ] with Ketones in SO <sub>2</sub> .....	37
2.4.1 Reaction of [SF <sub>3</sub> ][AsF <sub>6</sub> ] with Acetone .....	38
2.4.1.1 Reaction of [SF <sub>3</sub> ][AsF <sub>6</sub> ] with Excess Acetone.....	38
2.4.1.2 Reaction of [SF <sub>3</sub> ][AsF <sub>6</sub> ] with Three Equivalents of Acetone .....	38
2.4.1.3 Reaction of [SF <sub>3</sub> ][AsF <sub>6</sub> ] with Three Equivalents of Acetone .....	39
2.4.1.4 Reaction of [SF <sub>3</sub> ][AsF <sub>6</sub> ] with One Equivalent of Acetone.....	39
2.4.2 Reaction of [SF <sub>3</sub> ][AsF <sub>6</sub> ] with Cyclopentanone.....	40
2.4.2.1 Reaction of [SF <sub>3</sub> ][AsF <sub>6</sub> ] with Two Equivalents of Cyclopentanone...	40
2.4.2.2 Reaction of [SF <sub>3</sub> ][AsF <sub>6</sub> ] with One Equivalent of Cyclopentanone.....	41
2.4.3 Reaction of [SF <sub>3</sub> ][AsF <sub>6</sub> ] with 2-Adamantanone .....	41
2.4.3.1 Reaction of [SF <sub>3</sub> ][AsF <sub>6</sub> ] with Two Equivalents of 2-Adamantanone .....	41
2.4.3.2 Reaction of [SF <sub>3</sub> ][AsF <sub>6</sub> ] with One Equivalent of 2-Adamantanone .....	42
2.5 Synthesis of Protonated Ketones .....	43
2.5.1 Synthesis of [HO=C <sub>10</sub> H <sub>14</sub> ][AsF <sub>6</sub> ].....	43
2.5.2 Synthesis of [HO=C <sub>10</sub> H <sub>14</sub> ][SbF <sub>6</sub> ].....	44

2.5.3	Synthesis of $[\text{HO}=\text{C}_5\text{H}_8][\text{AsF}_6]$ .....	45
2.5.4	Synthesis of $[\text{HO}=\text{C}_5\text{H}_8][\text{SbF}_6]$ .....	45
2.5.5	Synthesis of $[\text{HO}=\text{C}(\text{CH}_3)_2][\text{SbF}_6]$ .....	46
2.5.6	Synthesis of $[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_2]_3[\text{HO}=\text{C}(\text{CH}_3)_2]_3[\text{SbF}_6]_5\text{F}$ .....	46
2.6	Synthesis of Protonated Aldehydes .....	47
2.6.1	Synthesis of $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2][\text{SbF}_6]$ .....	47
2.6.2	Synthesis of $[\text{H}(\text{O}=\text{CHCH}_3)_2][\text{SbF}_6]$ and $[\text{HO}=\text{CHCH}_3][\text{SbF}_6]$ .....	48
2.7	Synthesis of the Adducts of $\text{AsF}_5$ with Ketones .....	49
2.7.1	Synthesis of $\text{AsF}_5 \cdot \text{O}=\text{C}(\text{CH}_3)_2$ .....	49
2.7.2	Synthesis of $\text{AsF}_5 \cdot \text{O}=\text{C}_5\text{H}_8$ .....	50
2.7.3	Synthesis of $\text{AsF}_5 \cdot \text{O}=\text{C}_{10}\text{H}_{14}$ .....	50
2.8	Single-Crystal X-ray Diffraction .....	51
2.8.1	Low-Temperature Crystal Mounting .....	51
2.8.2	Data Collection and Reduction .....	52
2.8.3	Structure Solution and Refinement .....	53
2.9	Raman Spectroscopy.....	54
2.10	NMR Spectroscopy .....	54
2.11	Computational Details .....	55
<b>3.</b>	<b>Lewis Acid-Base Interactions Between <math>\text{SF}_4</math> and Acetone and 2-Adamantanone...</b>	<b>62</b>

Table 6.5 Calculated Energies (kJ/mol) of the HOMO and LUMO for the $\text{AsF}_5 \cdot \text{O}=\text{R}$ Adducts and the Protonated Ketones $[\text{H}(\text{O}=\text{R})_x]^+$ ( $x = 1$ or $2$ ; $\text{R} = \text{C}(\text{CH}_3)_2$ , $\text{C}_5\text{H}_8$ , $\text{C}_{10}\text{H}_{14}$ ) .....	190
Table 7.1 Calculated Energies (kJ/mol) of the HOMO and LUMO for Acetone, $[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_x]^+$ ( $x = 1, 2$ ), $\text{AsF}_5 \cdot \text{O}=\text{C}(\text{CH}_3)_2$ , and $[\text{SF}_3 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_x]^+$ ( $x = 1-3$ ) .....	196
Table A.1.1 Observed and Calculated (B3LYP/aug-cc-pVTZ) Raman Frequencies For $[\text{SF}_4 \cdot \text{O}=\text{C}(\text{CH}_3)_2]_2$ , $\text{SF}_4 \cdot [\text{O}=\text{C}(\text{CH}_3)_2]_2$ , and $\text{O}=\text{C}(\text{CH}_3)_2$ .....	198
Table A.2.1 Bond Lengths (Å), Hydrogen Bonds (Å), and Bond Angles (°) of $[\text{HO}=\text{C}_{10}\text{H}_{14}][\text{AsF}_6]$ .....	200
Table A.2.2 Calculated Bond Lengths and Bond Angles of $\text{O}=\text{C}_{10}\text{H}_{14}$ .....	205
Table A.2.3 Bond Lengths (Å), Hydrogen Bonds (Å), and Bond Angles (°) of $[\text{HO}=\text{C}_5\text{H}_8][\text{PnF}_6]$ , $\text{Pn} = \text{As}, \text{Sb}$ .....	204
Table A.2.4 Calculated Bond Lengths and Bond Angles of $\text{O}=\text{C}_5\text{H}_8$ .....	206
Table A.2.5 Bond Lengths (Å), Hydrogen Bonds (Å), and Bond Angles (°) of $[\text{HO}=\text{C}(\text{CH}_3)_2][\text{SbF}_6]$ .....	207
Table A.2.6 Bond Lengths (Å), Hydrogen Bonds (Å), and Bond Angles (°) of $[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_2]_3[\text{HO}=\text{C}(\text{CH}_3)_2]_3[\text{SbF}_6]_5\text{F}$ .....	210
Table A.2.7 Calculated Bond Lengths and Bond Angles of $\text{O}=\text{C}(\text{CH}_3)_2$ .....	212
Table A.2.8 Bond Lengths (Å), Hydrogen Bonds (Å), and Bond Angles (°) of $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2][\text{SbF}_6]$ .....	213
Table A.2.9 Calculated Bond Lengths (Å) and Bond Angles (°) of $\text{O}=\text{CHC}_6\text{H}_5$ .....	214
Table A.2.10 Bond Lengths (Å), Hydrogen Bonds (Å), and Bond Angles (°) of $[\text{H}(\text{O}=\text{CHCH}_3)_2][\text{SbF}_6]$ .....	214
Table A.2.11 Calculated Bond Lengths and Bond Angles of $\text{O}=\text{CHCH}_3$ .....	215
Table A.2.12 Observed and Calculated (B3LYP/aug-cc-pVTZ) Frequencies for 2-Adamantanone ( $\text{O}=\text{C}_{10}\text{H}_{14}$ ), $[\text{HO}=\text{C}_{10}\text{H}_{14}][\text{AsF}_6]$ , and $[\text{HO}=\text{C}_{10}\text{H}_{14}][\text{SbF}_6]$ .....	216
Table A.2.13 Observed and Calculated (B3LYP/aug-cc-pVTZ) Frequencies for Cyclopentanone ( $\text{O}=\text{C}_5\text{H}_8$ ), $[\text{HO}=\text{C}_5\text{H}_8][\text{AsF}_6]$ , and $[\text{HO}=\text{C}_5\text{H}_8][\text{SbF}_6]$ .....	220
Table A.2.14 Observed and Calculated (B3LYP/aug-cc-pVTZ) Frequencies for Acetone ( $\text{O}=\text{C}(\text{CH}_3)_2$ ) and $[\text{HO}=\text{C}(\text{CH}_3)_2][\text{SbF}_6]$ .....	223
Table A.2.15 Observed and Calculated (B3LYP/cc-pVTZ) Frequencies for Benzaldehyde ( $\text{O}=\text{CHC}_6\text{H}_5$ ) and $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2][\text{SbF}_6]$ .....	225
Table A.2.16 Observed and Calculated (B3LYP/aug-cc-pVTZ) Frequencies for Acetaldehyde ( $\text{O}=\text{CHCH}_3$ ), $[\text{H}(\text{O}=\text{CHCH}_3)_2][\text{SbF}_6]$ , and $[\text{H}(\text{O}=\text{CHCH}_3)_2]^+$ .....	229
Table A.2.17 Observed and Calculated (B3LYP/aug-cc-pVTZ) Frequencies for Acetaldehyde ( $\text{O}=\text{CHCH}_3$ ), $[\text{HO}=\text{CHCH}_3][\text{SbF}_6]$ , and $[\text{HO}=\text{CHCH}_3]^+$ ...	232

Table A.2.18 Natural Bond Order (NBO) Valences, Bond Orders, and Natural Population Analysis (NPA) Charges <sup>a</sup> for 2-Adamantanone (O=C <sub>10</sub> H <sub>14</sub> ) and Cation [HO=C <sub>10</sub> H <sub>14</sub> ] <sup>+</sup> in [HO=C <sub>10</sub> H <sub>14</sub> ][AsF <sub>6</sub> ] .....	236
Table A.2.19 Natural Bond Order (NBO) Valences, Bond Orders, and Natural Population Analysis (NPA) Charges <sup>a</sup> for Cyclopentanone (O=C <sub>5</sub> H <sub>8</sub> ) and Cation [HO=C <sub>5</sub> H <sub>8</sub> ] <sup>+</sup> in [HO=C <sub>5</sub> H <sub>8</sub> ][AsF <sub>6</sub> ] and [HO=C <sub>5</sub> H <sub>8</sub> ][SbF <sub>6</sub> ] .....	239
Table A.2.20 Natural Bond Order (NBO) Valences, Bond Orders, and Natural Population Analysis (NPA) Charges <sup>a</sup> for Acetone (O=C(CH <sub>3</sub> ) <sub>2</sub> ), Cation [HO=C(CH <sub>3</sub> ) <sub>2</sub> ] <sup>+</sup> in [HO=C(CH <sub>3</sub> ) <sub>2</sub> ][SbF <sub>6</sub> ], and Cation [H(O=C(CH <sub>3</sub> ) <sub>2</sub> ) <sub>2</sub> ] <sup>+</sup> in [H{O=C(CH <sub>3</sub> ) <sub>2</sub> } <sub>2</sub> ] <sub>3</sub> [HO=C(CH <sub>3</sub> ) <sub>2</sub> ] <sub>3</sub> [SbF <sub>6</sub> ] <sub>5</sub> F .....	242
Table A.2.21 Natural Bond Order (NBO) Valences, Bond Orders, and Natural Population Analysis (NPA) Charges <sup>a</sup> for Benzaldehyde (O=CHC <sub>6</sub> H <sub>5</sub> ) and Cation [H(O=CHC <sub>6</sub> H <sub>5</sub> ) <sub>2</sub> ] <sup>+</sup> in [H(O=CHC <sub>6</sub> H <sub>5</sub> ) <sub>2</sub> ][SbF <sub>6</sub> ] .....	244
Table A.2.22 Natural Bond Order (NBO) Valences, Bond Orders, and Natural Population Analysis (NPA) Charges <sup>a</sup> for Acetaldehyde (O=CHCH <sub>3</sub> ), Cation [H(O=CHCH <sub>3</sub> ) <sub>2</sub> ] <sup>+</sup> in [H(O=CHCH <sub>3</sub> ) <sub>2</sub> ][SbF <sub>6</sub> ], and cation [HO=CHCH <sub>3</sub> ] <sup>+</sup> in [HO=CHCH <sub>3</sub> ][SbF <sub>6</sub> ].....	247
Table A.3.1 Calculated Bond Lengths (Å) and Bond Angles (°) of AsF <sub>5</sub> ·O=C <sub>10</sub> H <sub>14</sub> .....	248
Table A.3.2 Calculated Bond Lengths (Å) and Bond Angles (°) of AsF <sub>5</sub> ·O=C <sub>5</sub> H <sub>8</sub> .....	249
Table A.3.3 Calculated Bond Lengths (Å) and Bond Angles (°) of AsF <sub>5</sub> ·O=C(CH <sub>3</sub> ) <sub>2</sub> .....	250
Table A.3.4 Observed and Calculated (B3LYP/cc-pVTZ) Frequencies for 2-Adamantanone (O=C <sub>10</sub> H <sub>14</sub> ) and AsF <sub>5</sub> ·O=C <sub>10</sub> H <sub>14</sub> .....	251
Table A.3.5 Observed and Calculated Frequencies for Cyclopentanone (O=C <sub>5</sub> H <sub>8</sub> ) and AsF <sub>5</sub> ·O=C <sub>5</sub> H <sub>8</sub> .....	254
Table A.3.6 Observed and Calculated (B3LYP/aug-cc-pVTZ) Frequencies for Acetone (O=C(CH <sub>3</sub> ) <sub>2</sub> ) and AsF <sub>5</sub> ·O=C(CH <sub>3</sub> ) <sub>2</sub> .....	256
Table A.3.7 Natural Bond Order (NBO) Valences, Bond Orders, and Natural Population Analysis (NPA) Charges <sup>a</sup> for Acetone (O=C(CH <sub>3</sub> ) <sub>2</sub> ) and AsF <sub>5</sub> ·O=C(CH <sub>3</sub> ) <sub>2</sub> .....	260
Table A.3.8 Natural Bond Order (NBO) Valences, Bond Orders, and Natural Population Analysis (NPA) Charges <sup>a</sup> for Cyclopentanone (O=C <sub>5</sub> H <sub>8</sub> ) and AsF <sub>5</sub> ·O=C <sub>5</sub> H <sub>8</sub> .....	263
Table A.3.9 Natural Bond Order (NBO) Valences, Bond Orders, and Natural Population Analysis (NPA) Charges <sup>a</sup> for 2-Adamantanone (O=C <sub>10</sub> H <sub>14</sub> ) and AsF <sub>5</sub> ·O=C <sub>10</sub> H <sub>14</sub> .....	266

## List of Figures

Figure 1.1	Structure of [18]crown-6 chelated to the potassium cation, $[K^+]$ , and the isolated fluoride anion, $[F]^-$ .....	3
Figure 1.2	Structure of 1-chloromethyl-4-fluorodiazoniabicyclo-[2.2.2]octane bis(tetrafluoroborate), also known as Selectfluor™ .....	3
Figure 1.3	Common deoxofluorinating reagents used include: a) Diethylaminosulfur trifluoride (DAST), b) Bis(2-methoxyethyl)aminosulfur trifluoride (Deoxo-Fluor), c) Diethylaminodifluorosulfonium tetrafluoroborate (XtalFluor-E), d) Morpholino-difluorosulfonium tetrafluoroborate (XtalFluor-M), e) 4-tert-butyl-2,6-dimethylphenyl- sulfur trifluoride (Fluolead) .....	12
Figure 1.4	Thermal ellipsoid plot of the X-ray crystal structure of $[HNC_5H_5]^+F^- \cdot SF_4$ taken from Ref. 46. Thermal ellipsoids are set at the 50% probability level. The bridging interaction between the fluoride and $SF_4$ , $F_4S \cdots [F]^-$ , has contacts of 2.6826(9) and 2.7739(9) Å. The N(1)H $\cdots$ F(9) distance is 2.4367(13) Å .....	16
Figure 1.5	Thermal ellipsoid plot of the X-ray crystal structure of $C_8H_{10}N_4O_2 \cdot 2SF_4 \cdot HF$ taken from Ref. 50. Thermal ellipsoids are set at the 50% probability level. The HF(9) is bridging S(2) of $SF_4$ (2.7932(15) Å) and the Lewis basic site N(4) of caffeine .....	17
Figure 2.1	Glass vacuum line system equipped with J. Young PTFE/glass stopcocks, a Heise and thermocouple gauge, and vacuum/nitrogen manifolds (Adapted from Jared Nieboer's M.Sc. Thesis, Ref. 2) .....	28
Figure 2.2	Metal vacuum system; (A) MKS type 626A capacitance manometer (0-1000 Torr), (B) MKS Model PDR-5B pressure transducers (0-10 Torr), (C) 3/8-in. stainless- steel high-pressure valves (Autoclave Engineers, 30VM6071), (D) 316 stainless-steel cross (Autoclave Engineers, CX6666), (E) 316 stainless-steel L-piece (Autoclave Engineers, CL6600), (F) 316 stainless steel T-piece (Autoclave engineers, CT6660), (G) 3/8-in o.d., 1/8-in. i.d. nickel connectors, (H) 1/8-in o.d., 1/8-in. i.d. nickel tube. (from Jared Nieboer's M.Sc. thesis, Ref. 2) .....	29
Figure 2.3	Diagrams of (a) a 1/4-in. o.d. and (b) 4-mm o.d. FEP reactor fitted with a Kel-F valve. (from Jared Nieboer's M.Sc. thesis, Ref. 2) .....	31
Figure 2.4	A 3/4-in. o.d. FEP vessel equipped with a stainless steel valve and a FEP T-piece connection for the distillation of HF into reactors. (from Jared Nieboer's M.Sc. thesis, Ref. 2) .....	33
Figure 2.5	Low-temperature crystal-mounting setup, consisting of a 10.5 L Dewar, equipped with a foam stopper, a glass nitrogen inlet, a silvered glass cold nitrogen outlet with an 11 cm long aluminum trough (2 cm o.d.). (Adapted from Jared Nieboer's M.Sc. Thesis, Ref. 2) .....	52
Figure 3.1	a) Thermal ellipsoid plots of $(SF_4 \cdot O=C(CH_3)_2)_2$ . Thermal ellipsoids are set at the 50% probability level. b) Geometry-optimized gas-phase structure of $[SF_4 \cdot O=C(CH_3)_2]_2$ at the B3LYP/aug-cc-pVTZ level of theory .....	67

Figure 3.2	Geometry-optimized gas-phase structure of $\text{SF}_4 \cdot [\text{O}=\text{C}(\text{CH}_3)_2]_2$ at the B3LYP/aug-cc-pVTZ level of theory.....	69
Figure 3.3	Raman spectrum of $\text{O}=\text{C}(\text{CH}_3)_2$ , $\text{SF}_4 \cdot [\text{O}=\text{C}(\text{CH}_3)_2]_2$ and $[\text{SF}_4 \cdot \text{O}=\text{C}(\text{CH}_3)_2]_2$ at $-110^\circ\text{C}$ . Symbols denote bands arising from FEP sample tube (*), and an instrumental artifact (#).....	72
Figure 3.4	Thermal ellipsoid plots of $\text{SF}_4 \cdot (\text{O}=\text{C}_{10}\text{H}_{14}) \cdot (\text{HF})$ . Thermal ellipsoids are set at the 50% probability level .....	78
Figure 4.1	$^{19}\text{F}$ NMR spectrum (282.40 MHz) of $[\text{SF}_3][\text{AsF}_6]$ dissolved in excess acetone at $-80^\circ\text{C}$ . Reaction warmed from $-80^\circ\text{C}$ to RT. Externally referenced to $\text{CFCl}_3$ at RT .....	87
Figure 4.2	$^{19}\text{F}$ NMR spectrum (282.40 MHz) of $\text{SF}_4$ in $\text{SO}_2$ at $-70^\circ\text{C}$ . Externally referenced to $\text{CFCl}_3$ at RT .....	89
Figure 4.3	$^{19}\text{F}$ NMR spectrum (282.40 MHz) of $\text{SF}_4$ in excess acetone at $-70^\circ\text{C}$ . Sample was warmed to RT for 1 h. Externally referenced to $\text{CFCl}_3$ at RT .....	90
Figure 4.4	$^{19}\text{F}$ NMR spectra (282.40 MHz) showing the progress of the reaction of $[\text{SF}_3][\text{AsF}_6]$ with three molar equivalents of acetone in $\text{SO}_2$ at $-70^\circ\text{C}$ . All spectra were externally referenced to $\text{CFCl}_3$ at RT.....	93
Figure 4.5	$^1\text{H}$ NMR spectra (300.13 MHz) showing the progress of the reaction of $[\text{SF}_3][\text{AsF}_6]$ with three equivalents of acetone at $-70^\circ\text{C}$ in $\text{SO}_2$ . Spectra were externally referenced to $\text{Si}(\text{CH}_3)_4$ at RT.....	96
Figure 4.6	$^{19}\text{F}$ NMR spectra (282.40 MHz) showing the progress of the reaction of $[\text{SF}_3][\text{AsF}_6]$ with 2.5 molar equivalents of acetone in $\text{SO}_2$ at $-70^\circ\text{C}$ . All spectra were externally referenced to $\text{CFCl}_3$ at RT.....	99
Figure 4.7	$^{19}\text{F}$ NMR spectra (282.40 MHz) showing the progress of the reaction of $[\text{SF}_3][\text{AsF}_6]$ with acetone in $\text{SO}_2$ at $-70^\circ\text{C}$ in a 1:1 molar ratio. All spectra were externally referenced to $\text{CFCl}_3$ at RT .....	102
Figure 4.8	$^1\text{H}$ NMR spectrum (300.13 MHz) at $-70^\circ\text{C}$ showing the reaction of $[\text{SF}_3][\text{AsF}_6]$ with acetone in $\text{SO}_2$ in a 1:1 molar ratio after having been warmed to RT for 45 min. Externally referenced to $\text{Si}(\text{CH}_3)_4$ at RT.....	104
Figure 4.9	$^{19}\text{F}$ NMR spectra (282.40 MHz) showing the progress of the reaction of $[\text{SF}_3][\text{AsF}_6]$ with 2.2 molar equivalents of cyclopentanone in $\text{SO}_2$ at $-70^\circ\text{C}$ . All spectra were externally referenced to $\text{CFCl}_3$ at RT.....	106
Figure 4.10	$^1\text{H}$ NMR spectra (300.13 MHz) showing the progress of the reaction of $[\text{SF}_3][\text{AsF}_6]$ with 2.2 molar equivalents of cyclopentanone in $\text{SO}_2$ at $-70^\circ\text{C}$ . All spectra were externally referenced to $\text{Si}(\text{CH}_3)_4$ at RT .....	109
Figure 4.11	$^{19}\text{F}$ NMR spectra (282.40 MHz) showing the progress of the reaction of $[\text{SF}_3][\text{AsF}_6]$ with 1.4 molar equivalents of cyclopentanone in $\text{SO}_2$ at $-70^\circ\text{C}$ . All spectra were externally referenced to $\text{CFCl}_3$ at RT.....	112
Figure 4.12	$^1\text{H}$ NMR spectra (300.13 MHz) showing the progress of the reaction of $[\text{SF}_3][\text{AsF}_6]$ with cyclopentanone in $\text{SO}_2$ at $-70^\circ\text{C}$ in a 1:1.4 molar ratio. All spectra were externally referenced to $\text{Si}(\text{CH}_3)_4$ at RT .....	115

Figure 4.13	$^{19}\text{F}$ NMR spectrum (282.40 MHz) showing the reaction of $[\text{SF}_3][\text{AsF}_6]$ with two molar equivalents of 2-adamantanone in $\text{SO}_2$ at $-40^\circ\text{C}$ . The reaction was briefly warmed to $-10^\circ\text{C}$ to dissolve the product. Externally referenced to $\text{CFCl}_3$ at RT.....	117
Figure 4.14	$^1\text{H}$ NMR spectra (300.13 MHz) showing the reaction of $[\text{SF}_3][\text{AsF}_6]$ with 2 equivalents of 2-adamantanone in $\text{SO}_2$ at $-40^\circ\text{C}$ after having been warmed to $-10^\circ\text{C}$ compared to 2-adamantanone in $\text{SO}_2$ at $-70^\circ\text{C}$ . Externally referenced to $\text{Si}(\text{CH}_3)_4$ at RT .....	118
Figure 4.15	$^{19}\text{F}$ NMR spectra (282.40 MHz) showing the progress of the reaction of $[\text{SF}_3][\text{AsF}_6]$ with 2-adamantanone in $\text{SO}_2$ at $-70^\circ\text{C}$ in a 1:1 molar ratio. All spectra were externally referenced to $\text{CFCl}_3$ at RT.....	121
Figure 4.16	Optimized gas-phase geometries and energies of possible intermediates in the deoxofluorination reaction: a) $[\text{SF}_3\cdot\text{O}=\text{C}(\text{CH}_3)_2]^+$ , b) $[\text{SF}_3\cdot\{\text{O}=\text{C}(\text{CH}_3)_2\}_2]^+$ , c) $[\text{SF}_3\cdot\{\text{O}=\text{C}(\text{CH}_3)_2\}_3]^+$ , d) $(\text{CH}_3)_2\text{FCOSF}_3$ , and e) $[(\text{CH}_3)_2\text{FCOSF}_2]^+$ .....	124
Figure 5.1	Structures of the previous protonated cyclopropylcarbinyl derivatives studied .....	131
Figure 5.2	a) Thermal ellipsoid plot of $[\text{HO}=\text{C}_{10}\text{H}_{14}][\text{AsF}_6]$ . Thermal ellipsoids are set at the 50% probability level. b) Geometry-optimized gas-phase structure of $[\text{HO}=\text{C}_{10}\text{H}_{14}]^+$ at the B3LYP/aug-cc-pVTZ level of theory .....	139
Figure 5.3	Thermal ellipsoid plots of a) $[\text{HO}=\text{C}_5\text{H}_8][\text{AsF}_6]$ , and b) $[\text{HO}=\text{C}_5\text{H}_8][\text{SbF}_6]$ . Thermal ellipsoids are set at the 50% probability level. c) Geometry-optimized gas-phase structure of $[\text{HO}=\text{C}_5\text{H}_8]^+$ at the B3LYP/aug-cc-pVTZ level of theory .....	140
Figure 5.4	Thermal ellipsoid plots of $[\text{HO}=\text{C}(\text{CH}_3)_2][\text{SbF}_6]$ . Thermal ellipsoids are set at the 50% probability level. b) Geometry-optimized gas-phase structure of $[\text{HO}=\text{C}(\text{CH}_3)_2]^+$ at the B3LYP/aug-cc-pVTZ level of theory.....	141
Figure 5.5	Thermal ellipsoid plots of the asymmetric unit $[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_2]_3[\text{HO}=\text{C}(\text{CH}_3)_2]_3[\text{SbF}_6]_5\text{F}$ . Thermal ellipsoids are set at the 50% probability level .....	142
Figure 5.6	Thermal ellipsoid plots of the $[\text{HO}=\text{C}(\text{CH}_3)_2]_3\text{F}$ unit in the $[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_2]_3[\text{HO}=\text{C}(\text{CH}_3)_2]_3[\text{SbF}_6]_5\text{F}$ salt. Thermal ellipsoids are set at the 50% probability level.....	143
Figure 5.7	Thermal ellipsoid plots of one of three $[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_2]^+$ cations in the $[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_2]_3[\text{HO}=\text{C}(\text{CH}_3)_2]_3[\text{SbF}_6]_5\text{F}$ salt. Thermal ellipsoids are set at the 50% probability level .....	143
Figure 5.8	a) Thermal ellipsoid plots of $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2][\text{SbF}_6]$ . Thermal ellipsoids are set at the 50% probability level. b) Geometry-optimized gas-phase structure of $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2]^+$ at the B3LYP/cc-pVTZ level of theory.....	148
Figure 5.9	a) Thermal ellipsoid plots of $[\text{H}(\text{O}=\text{CHCH}_3)_2][\text{SbF}_6]$ . Thermal ellipsoids are set at the 50% probability level. b) Geometry-optimized gas-phase structure of $[\text{H}(\text{O}=\text{CHCH}_3)_2]^+$ at the B3LYP/aug-cc-pVTZ level of theory.....	150

Figure 5.10 Protonated acetaldehyde, $[\text{HO}=\text{CHCH}_3]^+$ , energies in the a) <i>E</i> -configuration, $E = -404\,862$ kJ/mol, and b) <i>Z</i> -configuration, $E = -404\,859$ kJ/mol. Calculations done at the B3LYP/aug-cc-pVTZ level of theory.....	150
Figure 5.11 Raman spectrum of $\text{O}=\text{C}_{10}\text{H}_{14}$ , $[\text{HO}=\text{C}_{10}\text{H}_{14}][\text{SbF}_6]$ , and $[\text{HO}=\text{C}_{10}\text{H}_{14}][\text{AsF}_6]$ at $-100\text{ }^\circ\text{C}$ . Symbols denote bands arising from FEP sample tube (*), an instrumental artifact (#), $[\text{SbF}_6]^-$ vibrations ( $\dagger$ ), and $[\text{AsF}_6]^-$ vibrations ( $\ddagger$ ).....	153
Figure 5.12 Raman spectrum of $\text{O}=\text{C}_5\text{H}_8$ , $[\text{HO}=\text{C}_5\text{H}_8][\text{SbF}_6]$ , and $[\text{HxO}=\text{C}_5\text{H}_8][\text{AsF}_6]$ at $-100\text{ }^\circ\text{C}$ . Symbols denote bands arising from FEP sample tube (*), an instrumental artifact (#), $[\text{SbF}_6]^-$ vibrations ( $\dagger$ ), and $[\text{AsF}_6]^-$ vibrations ( $\ddagger$ ).....	154
Figure 5.13 Raman spectrum of $\text{O}=\text{C}(\text{CH}_3)_2$ and $[\text{HO}=\text{C}(\text{CH}_3)_2][\text{SbF}_6]$ at $-100\text{ }^\circ\text{C}$ . Symbols denote bands arising from FEP sample tube (*), an instrumental artifact (#), and $[\text{SbF}_6]^-$ vibrations ( $\dagger$ ).....	155
Figure 5.14 Raman spectrum of $\text{O}=\text{CHC}_6\text{H}_5$ and $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2][\text{SbF}_6]$ at $-100\text{ }^\circ\text{C}$ . Symbols denote bands arising from FEP sample tube (*), an instrumental artifact (#), and $[\text{SbF}_6]^-$ vibrations ( $\dagger$ ).....	157
Figure 5.15 Raman spectrum of $\text{O}=\text{CHCH}_3$ , $[\text{HO}=\text{CHCH}_3][\text{SbF}_6]$ , and $[\text{H}(\text{O}=\text{CHCH}_3)_2][\text{SbF}_6]$ at $-100\text{ }^\circ\text{C}$ . Symbols denote bands arising from FEP sample tube (*), an instrumental artifact (#), and $[\text{SbF}_6]^-$ vibrations ( $\dagger$ ).....	158
Figure 5.16 Molecular orbitals of acetone, protonated acetone, and hemiprotonated acetone. a) LUMO of acetone with $E = -18$ kJ/mol; b) LUMO of protonated acetone with $E = -189$ kJ/mol; c) LUMO of hemiprotonated acetone with $E = -596$ kJ/mol; d) HOMO of acetone with $E = -162$ kJ/mol; e) HOMO of protonated acetone with $E = -376$ kJ/mol; f) HOMO of hemiprotonated acetone with $E = -1203$ kJ/mol.....	162
Figure 5.17 Molecular orbitals of acetaldehyde and protonated acetaldehyde. a) LUMO of acetaldehyde with $E = -157$ kJ/mol; b) LUMO of protonated acetaldehyde with $E = -201$ kJ/mol; c) LUMO of hemiprotonated acetaldehyde with $E = -664$ kJ/mol; d) HOMO of acetaldehyde with $E = -216$ kJ/mol; e) HOMO of protonated acetaldehyde with $E = -382$ kJ/mol; f) HOMO of hemiprotonated acetaldehyde with $E = -1270$ kJ/mol.....	163
Figure 6.1 Structures of (a) the <i>E</i> -configuration of the adduct between $\text{BF}_3$ and benzaldehyde and (b) the adduct between $\text{AlCl}_3$ and tetramethylurea .....	170
Figure 6.2 Structures of the ketones used to form adducts with $\text{AsF}_5$ .....	171
Figure 6.3 Raman spectrum of $\text{O}=\text{C}(\text{CH}_3)_2$ and $\text{AsF}_5\cdot\text{O}=\text{C}(\text{CH}_3)_2$ at $-100\text{ }^\circ\text{C}$ . Symbols denote bands arising from FEP sample tube (*), an instrumental artifact (#), and the $\text{AsF}_5$ vibrations ( $\dagger$ ).....	176
Figure 6.4 Raman spectrum of $\text{O}=\text{C}_5\text{H}_8$ and $\text{AsF}_5\cdot\text{O}=\text{C}_5\text{H}_8$ at $-100\text{ }^\circ\text{C}$ . Symbols denote bands arising from FEP sample tube (*), an instrumental artifact (#), and the $\text{AsF}_5$ vibrations ( $\dagger$ ).....	177
Figure 6.5 Raman spectrum of $\text{O}=\text{C}_{10}\text{H}_{14}$ and $\text{AsF}_5\cdot\text{O}=\text{C}_{10}\text{H}_{14}$ at $-100\text{ }^\circ\text{C}$ . Symbols denote bands arising from FEP sample tube (*), an instrumental artifact (#), and the $\text{AsF}_5$ vibrations ( $\dagger$ ).....	178

Figure 6.6	$^{19}\text{F}$ NMR spectrum of (a) $\text{AsF}_5 \cdot \text{O}=\text{C}(\text{CH}_3)_2$ , (b) $\text{AsF}_5 \cdot \text{O}=\text{C}_5\text{H}_8$ , and (c) $\text{AsF}_5 \cdot \text{O}=\text{C}_{10}\text{H}_{14}$ (c) adducts in liquid $\text{SO}_2$ at $-70^\circ\text{C}$ . Externally referenced to $\text{CFCl}_3$ . The symbol (*) denotes the $\text{AsF}_5 \cdot \text{SO}_2$ signal .....	182
Figure 6.7	$^{19}\text{F}$ NMR spectrum of $\text{AsF}_5 \cdot \text{O}=\text{C}(\text{CH}_3)_2$ after warming to RT for 40 min. Externally referenced to $\text{CFCl}_3$ .....	184
Figure 6.8	Optimized gas-phase geometries of a) $\text{AsF}_5 \cdot \text{O}=\text{C}(\text{CH}_3)_2$ , b) $\text{AsF}_5 \cdot \text{O}=\text{C}_5\text{H}_8$ , and c) $\text{AsF}_5 \cdot \text{O}=\text{C}_{10}\text{H}_{14}$ .....	186

## List of Abbreviations

### General

$r_{\text{vdW}}$	van der Waals radius
$\chi$	electronegativity
aHF	anhydrous hydrogen fluoride
FEP	copolymer of perfluoroethylene and perfluoropropylene
Kel-F	polychlorotrifluoroethylene
PTFE	polytetrafluoroethylene
ax/eq	axial/equatorial
gem	geminal
IR	infrared
$\nu$	stretch
NMR	Nuclear Magnetic Resonance
o.d.	outer diameter
THF	tetrahydrofuran
RT	room temperature
LT	low temperature
DAST	diethylaminosulfur trifluoride

### X-ray Crystallography

$a, b, c, \alpha, \beta, \gamma$	cell parameters
$V$	volume
$\lambda$	wavelength
$Z$	molecules per unit cell
$\mu$	absorption coefficient
$\rho$	density
$R_1$	conventional agreement index
$wR_2$	weighted agreement index
$GooF$	goodness of fit

### Nuclear Magnetic Resonance

$\delta$	chemical shift
$J$	scalar coupling constant in Hertz
ppm	parts per million
TMS	tetramethylsilane

### Computational Methods

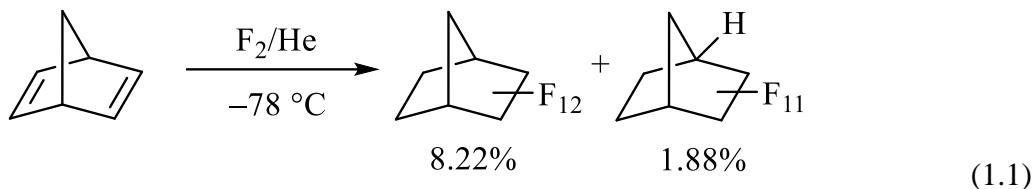

DFT	density functional theory
B3LYP	Becke, 3-parameter, Lee-Yang-Parr
aug-cc-pVTZ	augmented–correlation-consistent–polarized triple-zeta
NBO	natural bond order
NPA	natural population analysis
WBI	Wiberg bond index
HOMO	highest occupied molecular orbital
LUMO	lowest unoccupied molecular orbital

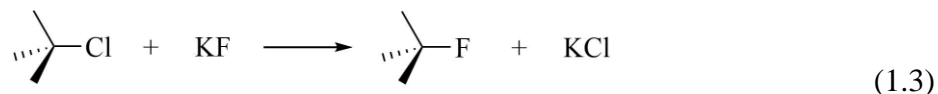

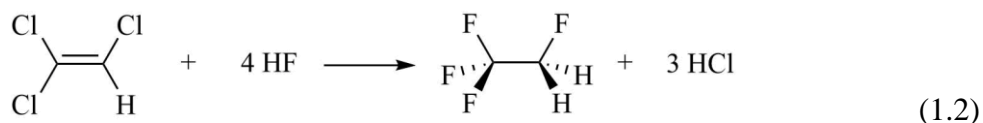

## 1. Introduction

### 1.1 Organofluorine Chemistry

Fluorine-containing molecules have found diverse applications in pharmaceutical, agrochemical, and materials chemistry, and as tracers for positron emission tomography.<sup>[1]</sup> In fact, approximately 30–40% of agrochemicals and 20–25% of pharmaceuticals on the market are estimated to contain fluorine atoms.<sup>[1a,2]</sup> The addition of fluorine to an organic molecule can drastically alter its chemical properties due to its small size ( $r_{\text{vdW}} = 1.47 \text{ \AA}$ ), high electronegativity ( $\chi = 4.0$  on the Pauling scale), strong C–F bond strength (bond dissociation energy of 441 kJ/mol), large dipole moment of C–F bonds (molecular dipole moment of 1.85 D for CH<sub>3</sub>F), and its ability to increase the lipophilicity of a molecule.<sup>[3]</sup> An active area of research includes selective C–F bond formation in organic molecules. The ability to selectively fluorinate a molecule, by means of electrophilic or nucleophilic fluorination, over different functional groups is inherently difficult.<sup>[4]</sup>

The use of highly oxidizing elemental fluorine (F<sub>2</sub>), diluted with nitrogen or helium, was one of the earliest methods used to prepare highly fluorinated organic molecules; however, these reactions are non-selective (see Equation 1.1) and often lead to fragmentation.<sup>[5]</sup> An important nucleophilic fluorinating agent is hydrogen fluoride (HF), commonly used in the production of chlorofluorocarbons (CFCs) or hydrofluorocarbons (HFCs) (see Equation 1.2).<sup>[6]</sup> The corrosive and toxic nature of HF, in conjunction with its low boiling point (19.5 °C), makes it difficult to work with under ambient conditions.

Olah and co-workers developed a stable and less volatile source of anhydrous HF (aHF) using a mixture of 70% HF with 30% pyridine (Olah's reagent) making it easier to handle under ambient conditions. Olah's reagent is a nucleophilic fluorinating agent stable up to 55 °C.<sup>[7]</sup>

The use of alkali metal fluorides, i.e., KF or CsF, offers a method of providing a  $[\text{F}]^-$  source that can be used in simple displacement reactions of other halides such as chloride or bromide (see Equation 1.3).<sup>[5]</sup> These metathesis reactions can sometimes require high temperatures and are selective depending on the substituents of the organic substrate and the solvent used. The larger the cation is, the more isolated the fluoride ion will be, which, consequently, increases its reactivity. Tetraalkyl ammonium salts, such as  $[\text{Me}_4\text{N}][\text{F}]$ , are alternatives to alkali metal fluorides where the nucleophilicity of the fluoride anion is enhanced by the weakly coordinating quaternary ammonium cation.<sup>[8]</sup> A challenge associated with the synthesis of these salts is the difficulty obtaining them in the anhydrous form. The nucleophilicity of alkali metal fluorides can be further enhanced by the use of chelating crown ethers, such as 18-crown-6, which encapsulate the cation of alkali metal fluorides leaving an unsaturated "naked" fluoride (see Figure 1.1). This allows nucleophilic substitution of other halides by  $[\text{F}]^-$  to take place under milder conditions with acceptable yields.<sup>[5]</sup>

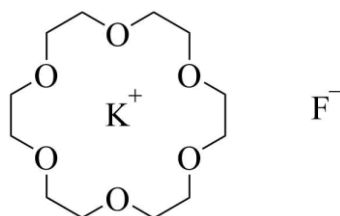

Figure 1.1 Structure of [18]crown-6 chelated to the potassium cation,  $[K^+]$ , and the isolated fluoride anion,  $[F]^-$ .

While nucleophilic fluorination is one of the most common methods used to introduce a fluoro-group, other reactions invoke the use of electrophilic fluorinating reagents.<sup>[9]</sup> These often employ a reagent that formally transfers a “[F]<sup>+</sup>” and directly converts C–H to C–F bonds. While the use of elemental fluorine is possible for electrophilic fluorination, easier-to-handle compounds have been developed and include perchloryl fluoride ( $FClO_3$ ), xenon difluoride ( $XeF_2$ ), and trifluoromethyl hypofluorite ( $CF_3OF$ ).<sup>[10]</sup> These compounds, however, still pose limitations that have prevented their widespread use including their potential as powerful oxidizing agents or difficulty producing large quantities. An alternative to these sources of fluorine are  $N^+–F$  fluorinating agents such as those from *N*-fluoropyridinium salts, including the well known 1-chloromethyl-4-fluoro-1,4-diazoniabicyclo[2.2.2]octane bis(tetrafluoroborate) (Selectfluor<sup>TM</sup>) (Figure 1.2).<sup>[9b,11]</sup>

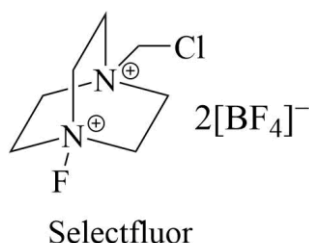

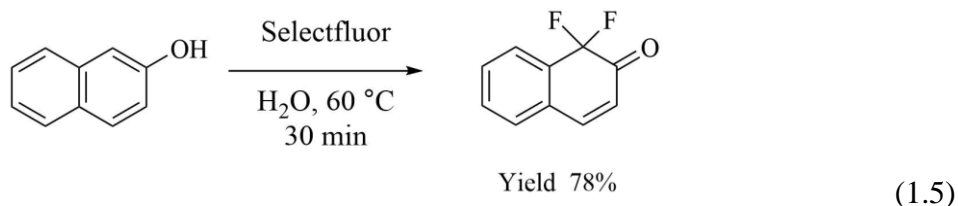

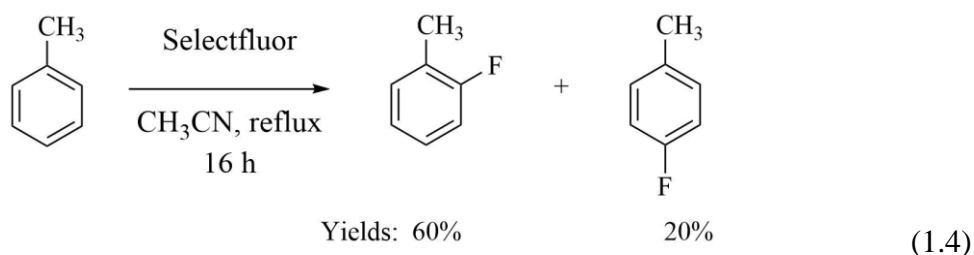

Figure 1.2 Structure of 1-chloromethyl-4-fluorodiazoniabicyclo[2.2.2]octane bis(tetrafluoroborate), also known as Selectfluor<sup>TM</sup>.

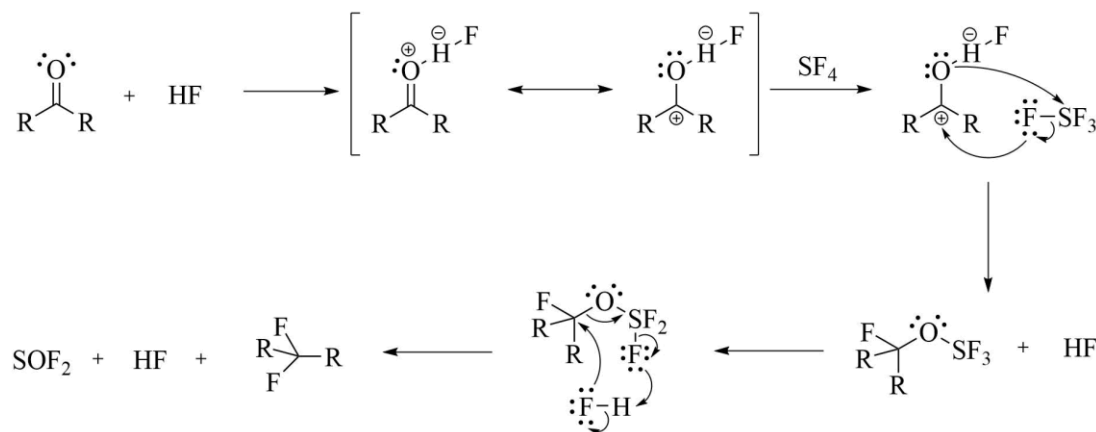

Selectfluor™ is a thermally stable reagent (up to 195 °C) and easy to handle for industrial use.<sup>[12]</sup> Reactions include the fluorination of toluene with Selectfluor™ in the presence of electron donating groups (Equation 1.4)<sup>[13]</sup> and electrophilic fluorination of organic substrates in aqueous media (Equation 1.5).<sup>[14]</sup>

### 1.1.1 Deoxofluorination Reactions

An effective method of fluorinating organic compounds involves the transformation of alcohols, ketones, and carboxylic acids to  $-\text{CF}$ ,  $-\text{CF}_2$ , and  $-\text{CF}_3$  groups, respectively, known as deoxofluorination.<sup>[15–19]</sup> One of the earliest nucleophilic fluorinating reagents used to perform deoxofluorination reactions is sulfur tetrafluoride,  $\text{SF}_4$ .<sup>[15–19]</sup> The first reactions which employed  $\text{SF}_4$  as a deoxofluorinating reagent involved reacting various ketones with  $\text{SF}_4$ , and was later expanded to include alcohols.<sup>[15]</sup> These reactions usually require specialized equipment, high temperatures ( $>100\text{ }^\circ\text{C}$ ), high pressures, and anhydrous conditions and have the potential to lead to undesirable by-products. Reaction mechanisms for deoxofluorination reactions of carbonyl groups and hydroxyl groups with  $\text{SF}_4$  have been postulated.<sup>[18–20]</sup> The earliest mechanism proposed by Hasek, Smith, and Engelhardt

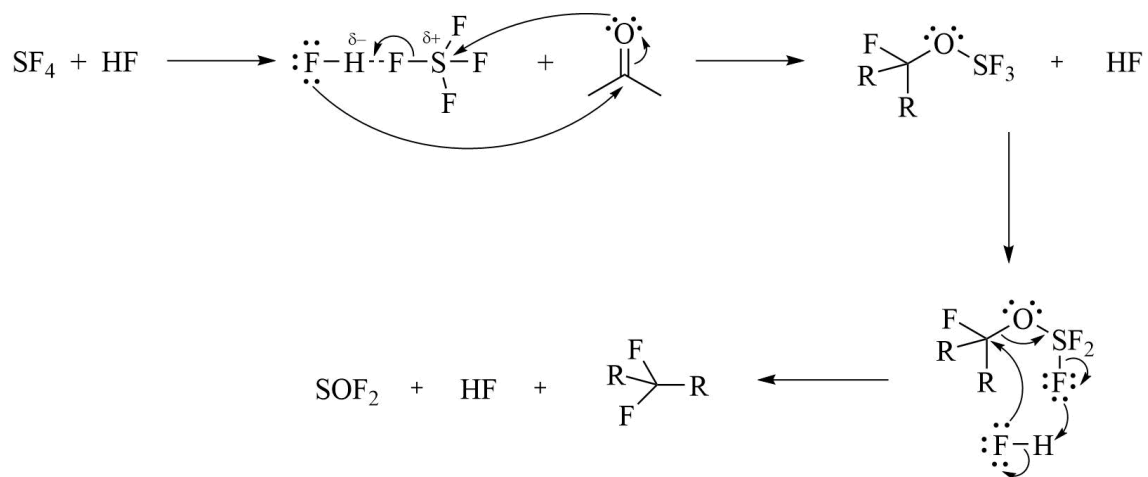

(DuPont) involves HF, as a catalyst, polarizing the C=O group allowing for SF<sub>4</sub> to add across the activated carbonyl group giving the alkoxysulfur trifluoride intermediate (ROSF<sub>3</sub>). This immediately reacts with HF to yield the respective difluoro compound, SOF<sub>2</sub>, and HF as products (Scheme 1.1).<sup>[15b]</sup> The addition of a catalytic amount of Lewis acid, including HF, BF<sub>3</sub>, AsF<sub>3</sub>, PF<sub>5</sub>, or TiF<sub>4</sub>, resulted in a large increase in the yield of the desired fluorinated compound.<sup>[15c]</sup>

Scheme 1.1 Reaction mechanism for the deoxofluorination of a carbonyl group with SF<sub>4</sub> in the presence of a catalytic amount of HF as proposed by Hasek, Smith, and Engelhardt, (Ref. 15b).

Martin and Kagan carried out reactions of SF<sub>4</sub> with carbonyl-containing steroids and showed the transformation of C=O groups to *gem*-difluorides.<sup>[17]</sup> It was found that significant amounts of HF rather than catalytic amounts allowed for more controlled fluorination reactions. They suggested that under conditions employing a catalytic amount of Lewis acid the reaction mechanism would follow that proposed by Hasek, Smith, and Engelhardt (Scheme 1.1). However, they also proposed two other possible mechanisms. One involved the formation of an adduct between HF and SF<sub>4</sub> (FH---F-SF<sub>3</sub>), in the

presence of excess HF, which then reacts with the carbonyl group to form the RFCOSF<sub>3</sub> intermediate (Scheme 1.2).

Scheme 1.2 Reaction mechanism for the deoxofluorination of a carbonyl group with SF<sub>4</sub> in the presence of large amounts of HF as proposed by Martin and Kagan (Ref. 17).

Alternatively, they proposed that SF<sub>4</sub> interacts with HF to form an ionic species consisting of [SF<sub>3</sub>]<sup>+</sup> and [HF<sub>2</sub>]<sup>-</sup>. The oxygen of the carbonyl group then undergoes electrophilic attack by [SF<sub>3</sub>]<sup>+</sup> followed by donation of a fluoride from [HF<sub>2</sub>]<sup>-</sup> to the carbon center generating the RFCOSF<sub>3</sub> intermediate. In both suggested mechanisms, the RFCOSF<sub>3</sub> intermediate is formed which then follows a similar mechanism to that proposed by Hasek, Smith, and Engelhardt.

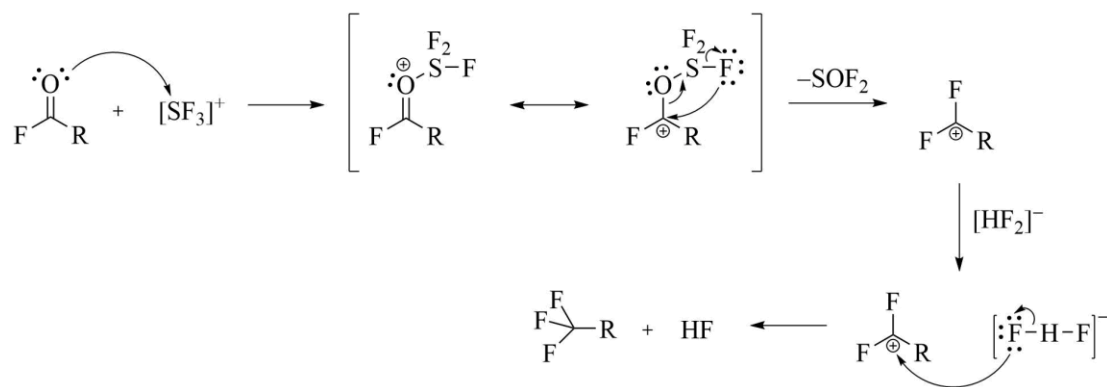

Dmowski investigated the effect of hydrogen fluoride concentration on the reaction of SF<sub>4</sub> with carboxylic acids and acyl fluorides and found the optimal concentration to be much higher than a catalytic amount, initially proposed by Hasek, Smith, and Engelhardt.<sup>[19a]</sup> The required amount of HF can be stoichiometric or a large excess to obtain maximum yield of deoxofluorinated product. It was also found that the basicity of the carbonyl group greatly affects the required HF concentration in deoxofluorination

reactions. Highly basic ketones require amounts of HF well above a 1:1 stoichiometry, with respect to the carbonyl compound, because they are more prone towards protonation by HF thereby slowing the deoxofluorination reaction due to a lack of HF in solution. By introducing more electron-withdrawing functional groups to the ketone the basicity is lowered, leaving more HF in solution, and therefore exhibiting a higher reactivity towards SF<sub>4</sub>.

With this information, Dmowski proposed a reaction mechanism for the deoxofluorination of ketones with SF<sub>4</sub> similar to the one by Martin and Kagan, whereby the presence of HF induces the dissociation of SF<sub>4</sub> into [SF<sub>3</sub>]<sup>+</sup> (Equation 1.7), a highly electrophilic cation believed to be the active species responsible for the deoxofluorination reaction.<sup>[19]</sup> Conductivity measurements had been carried out by Gillespie et al. showing the presence of an equilibrium concentration of [SF<sub>3</sub>]<sup>+</sup> and [HF<sub>2</sub>]<sup>-</sup> when SF<sub>4</sub> is dissolved in anhydrous HF with an estimated equilibrium constant of  $K = 4(2) \times 10^{-2}$  at 0 °C.<sup>[21]</sup>

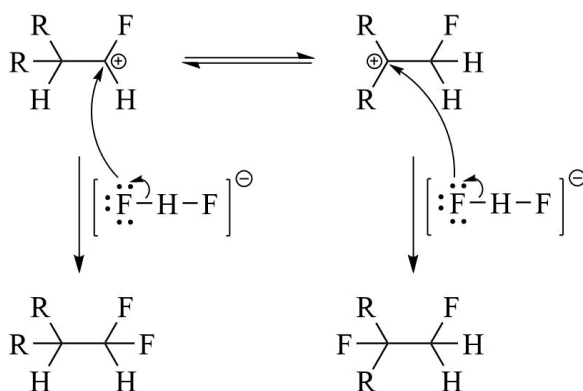

In an example of deoxofluorination of acyl fluorides, the carbonyl group undergoes electrophilic attack by the [SF<sub>3</sub>]<sup>+</sup> cation polarizing the C=O bond and forming the resonance-stabilized alkoxysulfur trifluoride cation. It is then suggested that a fluorine atom from the SF<sub>3</sub> substituent acts as a nucleophilic fluoride source and attacks the carbon center followed by elimination of SOF<sub>2</sub> and leaving the fluorocarbenium cation (Scheme 1.3). The highly reactive fluorocarbenium cation reacts with the fluoride source [HF<sub>2</sub>]<sup>-</sup> to give the resulting fluorinated compound where the carbonyl has been replaced by two fluorine atoms.<sup>[19]</sup>

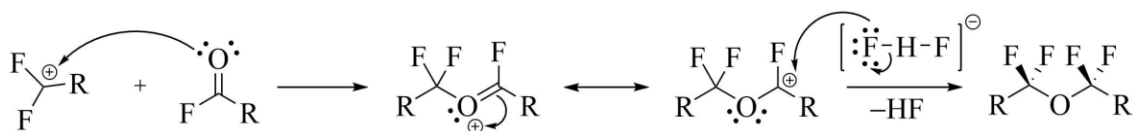

Scheme 1.3 Reaction mechanism for the deoxofluorination reaction of acetyl fluoride with  $\text{SF}_4$  in the presence of  $\text{HF}$  as proposed by Dmowski (Ref. 19).

In reactions of  $\text{SF}_4$  with aldehydes, depending on the substituents on the aldehyde, both 1,1- and 1,2-difluoroalkanes were obtained, which is in agreement with the formation of a carbocation that can isomerize to the tertiary carbenium cation (Scheme 1.4) followed by neutralization with fluoride from  $[\text{HF}_2]^-$ . Fluoroethers are known by-products of deoxofluorination reactions as a result of electrophilic attack of the fluorocarbenium ion on a second molecule of the carbonyl compound and subsequent neutralization with fluoride (from  $[\text{HF}_2]^-$ ) (see Scheme 1.5).

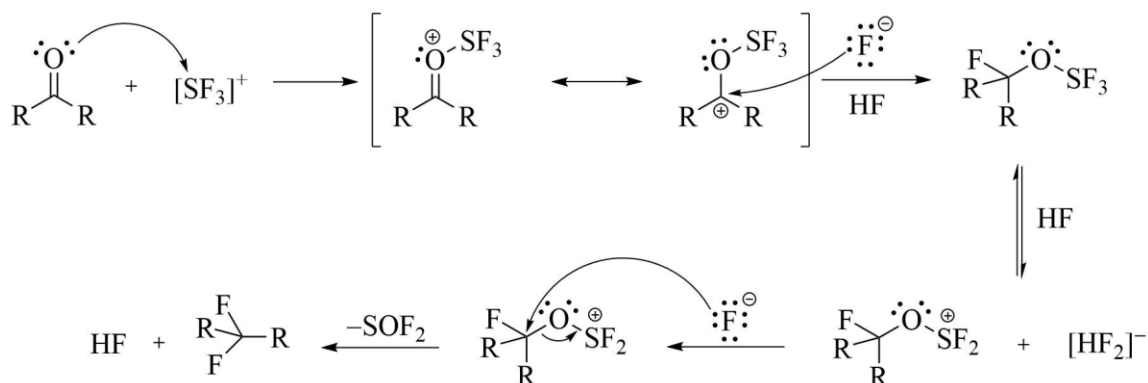

Scheme 1.4 Reaction mechanism showing the reversible isomerization of the fluorocarbenium cation followed by reaction with bifluoride,  $[\text{HF}_2]^-$ , to yield the 1,1-difluoroalkane and 1,2-difluoroalkane as shown by Dmowski (Ref. 19b).

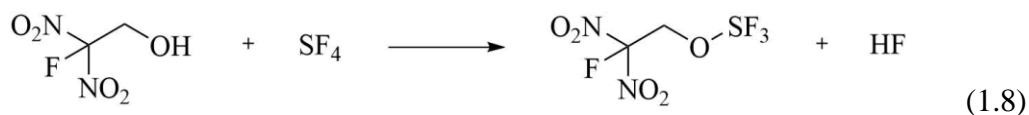

Scheme 1.5 Reaction mechanism for the synthesis of a fluoroether, a by-product in the deoxofluorination mechanism proposed by Dmowski (Ref. 19).

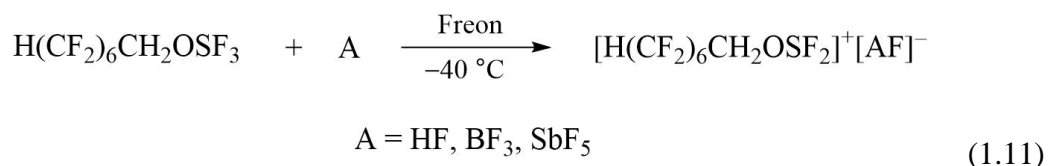

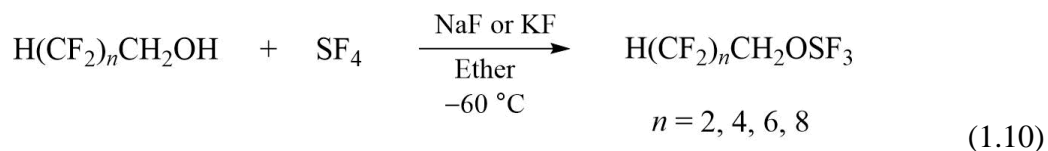

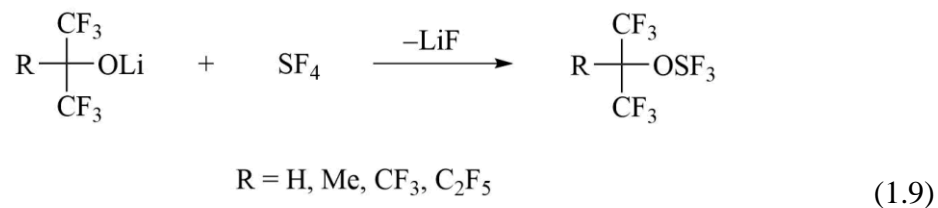

A slightly modified mechanism was proposed by Pustovit and Nazaretian and is shown in Scheme 1.6.<sup>[20]</sup> Similar to Dmowski's mechanism,  $[\text{SF}_3]^+$  is invoked (Equation 1.7) to polarize the carbonyl group generating the  $[\text{R}_2\text{C}-\text{O}-\text{SF}_3]^+$  cation. This carbocation can undergo nucleophilic attack by fluoride or  $[\text{HF}_2]^-$  to form the neutral  $\text{R}_2\text{FC}-\text{O}-\text{SF}_3$  which, in the presence of HF, is proposed to be in equilibrium with  $[\text{R}_2\text{FC}-\text{O}-\text{SF}_2]^+$ . In a side reaction, the  $[\text{R}_2\text{C}-\text{O}-\text{SF}_3]^+$  cation can also react with another carbonyl compound to form the fluoroethers previously mentioned. Once  $[\text{R}_2\text{FC}-\text{O}-\text{SF}_2]^+$  is present in solution, a nucleophile can attack the carbon atom by either an  $\text{S}_{\text{N}}1$  or  $\text{S}_{\text{N}}2$  reaction, depending on the reaction conditions and substituents present on the cation, eliminating  $\text{SOF}_2$  and yielding the fluorinated product.

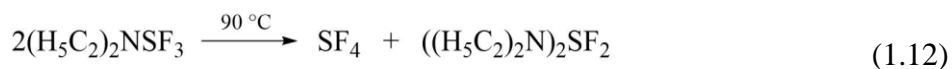

Scheme 1.6 Reaction mechanism for the deoxofluorination of a ketone with  $\text{SF}_4$  in HF as proposed by Pustovit and Nazaretian (Ref. 20).

The neutral alkoxysulfur trifluoride intermediate, ROSF<sub>3</sub>, has been hypothesized to exist; however, the isolation of only a few alkoxysulfur trifluorides has been reported. The reaction of SF<sub>4</sub> with 2-fluoro-2,2-dinitroethanol yielded 2-fluoro-2,2-dinitroethoxysulfur trifluoride (see Equation 1.8), which was solely characterized by <sup>19</sup>F NMR spectroscopy (singlet at −109.8 ppm (C–F); multiplet at 62.6 ppm (SF<sub>3</sub>)).<sup>[18]</sup> This species was shown to be readily hydrolyzed by moisture and immiscible in anhydrous HF. The alkoxysulfur trifluoride, an intermediate in each of the previously proposed deoxofluorination mechanisms, likely requires highly electron-withdrawing substituents to be stabilized. The inertness of (O<sub>2</sub>N)<sub>2</sub>FC–CH<sub>2</sub>OSF<sub>3</sub> towards aHF has been viewed as surprising, since the facile reaction of the ROSF<sub>3</sub> intermediate in the presence of HF has been postulated. In later work, the reaction of SF<sub>4</sub> with fluorinated lithium alkoxides resulted in the synthesis of polyfluorinated alkoxysulfur trifluorides (Equation 1.9).<sup>[22]</sup> A series of polyfluoroalkoxysulfur trifluorides were also been prepared by reaction of α,α,ω-trihdropolyfluoroalkanols with SF<sub>4</sub> in the presence of HF scavengers such as KF or NaF (Equation 1.10).<sup>[22]</sup> In the absence of the HF scavengers, the deoxofluorination product was exclusively obtained. The reaction of dodecafluoroheptyloxysulfur trifluorides with one equivalent of the Lewis acids HF, BF<sub>3</sub>, or SbF<sub>5</sub> at −40 °C in a Freon solution gave the respective dodecafluoroheptyloxydifluorosulfonium salts (Equation 1.11).<sup>[22]</sup> This cationic alkoxysulfur difluoride species is consistent with the intermediate in the deoxofluorination reaction mechanism proposed by Pustovit and Nazaretian in Scheme 1.6, where the neutral ROSF<sub>3</sub> intermediate is in equilibrium with [ROSF<sub>2</sub>]<sup>+</sup> in the presence of HF.<sup>[20]</sup>

Over the years, various derivatives of SF<sub>4</sub> have been synthesized which act as more convenient and easier to handle deoxofluorinating reagents compared to SF<sub>4</sub>. Diethylaminosulfur trifluoride (DAST) (see Figure 1.3) is used to selectively transform –OH and R<sub>2</sub>C=O functional groups to –F and R<sub>2</sub>CF<sub>2</sub> under relatively mild conditions.<sup>[23]</sup> It was later found that DAST decomposes upon warming above 90 °C into SF<sub>4</sub> and the extremely unstable bis(diethylamino)sulfur difluoride which, subsequently, results in detonation (see Equation 1.12).<sup>[24]</sup>

Bis(2-methoxyethyl)aminosulfur trifluoride (Deoxo-Fluor) (see Figure 1.3) was developed as a more thermally stable and safer substitute owing to its conformational rigidity imposed by the alkoxy groups.<sup>[25]</sup> The fluorination of ketones and aldehydes by Deoxo-Fluor results in the transformation of carbonyl groups to geminal difluorides with relatively good yields (see Equation 1.13). However, both DAST and Deoxo-Fluor are fuming liquids that react

violently with water and thus require a dry atmosphere to perform these reactions. In using these reagents, HF is generated as a by-product which is highly toxic and extremely corrosive.<sup>[26]</sup>

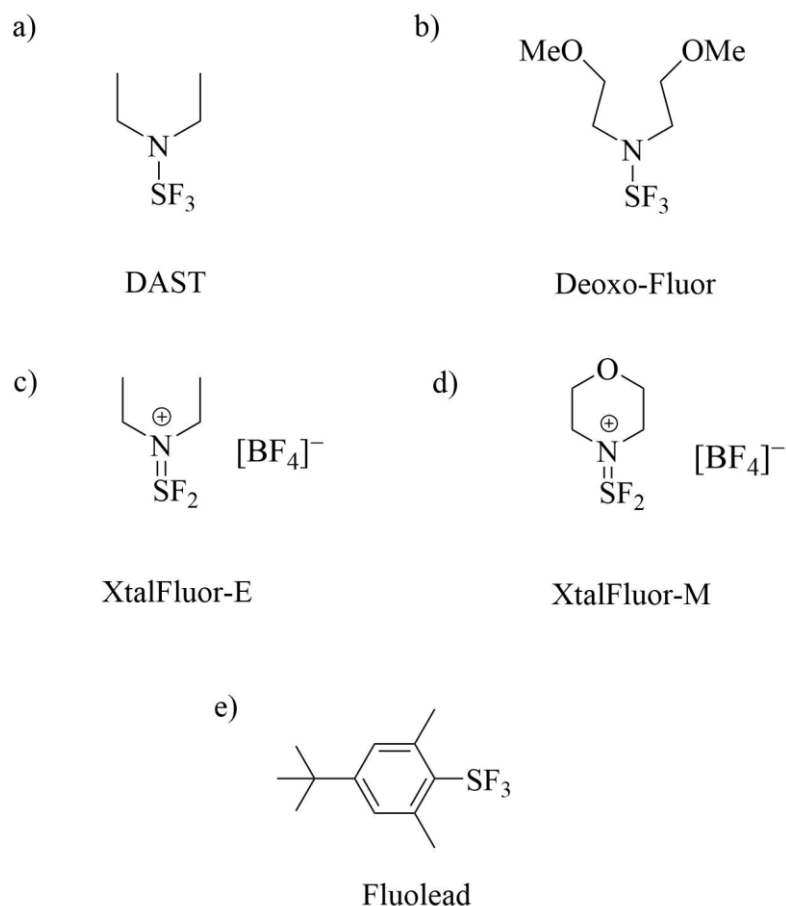

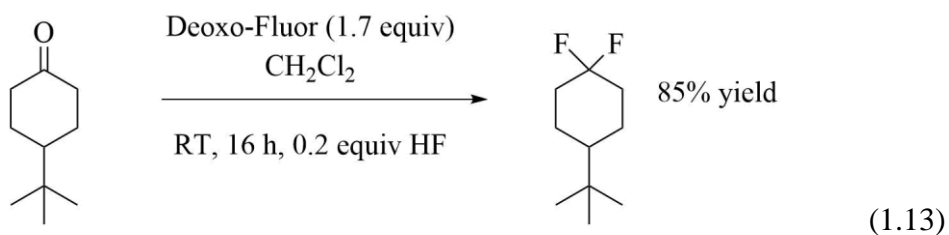

Figure 1.3 Common deoxofluorinating reagents used include: a) Diethylaminosulfur trifluoride (DAST), b) Bis(2-methoxyethyl)aminosulfur trifluoride (Deoxo-Fluor), c) Diethylaminodifluorosulfonium tetrafluoroborate (XtalFluor-E), d) Morpholinodifluorosulfonium tetrafluoroborate (XtalFluor-M), e) 4-*tert*-butyl-2,6-dimethylphenyl-sulfur trifluoride (Fluolead).

Difficulties associated with handling these reagents ( $\text{SF}_4$ , DAST, and Deoxo-Fluor) resulted in a push to synthesize deoxofluorinating reagents that are easier and safer to handle and more selective. Diethylaminodifluorosulfonium tetrafluoroborate (XtalFluor-E) and morpholinodifluorosulfonium tetrafluoroborate (XtalFluor-M) are crystalline fluorinating agents (see Figure 1.3) and allow for the formation of C–F bonds from a variety of oxygenated substrates, including aliphatic alcohols, carbonyl compounds, and carboxylic acid derivatives.<sup>[27]</sup> These reactions require a fluoride source, such as  $\text{Et}_3\text{N} \cdot 3\text{HF}$ , to proceed since the direct interaction between (dialkylamino)difluorosulfonium salts with oxygen bases does not contain a nucleophilic fluoride source. Using XtalFluor in reactions with alcohols results in deoxofluorination of the hydroxyl group with very few by-products compared to DAST or DeoxoFluor.<sup>[27a]</sup> As another alternative, derivatives of arylsulfur trifluorides, including 4-tert-butyl-2,6-dimethylphenylsulfur trifluoride (Fluolead), have been shown to be excellent deoxofluorinating reagents.<sup>[28]</sup> Fluolead (Figure 1.3) has been shown to be relatively unreactive towards small amounts of water in contrast to DAST and DeoxoFluor.<sup>[28c]</sup>

## 1.2 Sulfur Tetrafluoride

Sulfur tetrafluoride is a toxic, corrosive gas at room temperature (RT) with a melting point of  $-121\text{ }^\circ\text{C}$  and boiling point of  $-38\text{ }^\circ\text{C}$ . It is highly reactive with water forming hydrogen fluoride (HF) and thionyl fluoride ( $\text{SOF}_2$ ), and thus must be stored in a high-pressure and corrosion-resistant vessel. Sulfur tetrafluoride is one of several binary covalent fluorides of sulfur (besides  $\text{SF}_2$ ,  $\text{S}_2\text{F}_2$ ,  $\text{S}_2\text{F}_4$ ,  $\text{SF}_6$ , and  $\text{S}_2\text{F}_{10}$ ), and is a fluorinating agent capable of adding fluorine over various functional groups such as ketones, aldehydes,

carboxylic acids, and alcohols (*vide supra*).<sup>[29]</sup> Using the  $\text{pF}^-$  scale developed by Christe and Dixon for Lewis acidity,  $\text{SF}_4$  lies between  $\text{COF}_2$  (4.99) and  $\text{XeF}_4$  (5.71), two relatively mild fluoride-ion acceptors, at a  $\text{pF}^-$  value of 5.67, corresponding to a fluoride-ion affinity of  $56.7 \text{ kcal/mol} = 237 \text{ kJ/mol}$ .<sup>[30]</sup> Sulfur tetrafluoride is capable of acting as a Lewis acid towards strong fluoride-ion donors such as  $[\text{N}(\text{CH}_3)_4]\text{F}$  and  $\text{CsF}$  to form salts of the  $[\text{SF}_5]^-$  anion.<sup>[31,32]</sup> Due to the highly reactive and gaseous nature of  $\text{SF}_4$ , only recently has the solid-state structure been determined and found to agree with the seesaw geometry determined from gas-phase studies, vibrational spectroscopy, and NMR spectroscopy.<sup>[33–40]</sup> In the solid state,  $\text{SF}_4$  exhibits weak  $\text{F}_3\text{S}-\text{F}\cdots\text{SF}_4$  interactions, exclusively involving the more ionic axial fluorine atoms. The  $^{19}\text{F}$  NMR spectroscopy shows two chemical resonances as triplets for  $\text{SF}_4$  at 90 (F-axial) and 34 ppm (F-equatorial) ( $^2J(^{19}\text{F}-^{19}\text{F}) = 79 \text{ Hz}$ ) arising from the chemical inequivalence of the axial and equatorial fluorine ligands at low temperature (LT).

### 1.2.1 Adducts of $\text{SF}_4$ and Organic Nitrogen and Oxygen Bases

The Lewis acid behaviour of  $\text{SF}_4$  towards nitrogen-bases has been well documented in recent years. The first evidence for  $\text{SF}_4$  forming an adduct with a nitrogen base came from an early crude tensiometric study suggesting the 1:1 adduct formation with triethylamine and pyridine.<sup>[41]</sup> An elemental analysis study detected the  $\text{SF}_4 \cdot \text{NC}_5\text{H}_5$  adduct and claimed the existence of the  $\text{SF}_4 \cdot 2\text{NC}_5\text{H}_5$ ,  $\text{SF}_4 \cdot 4\text{NC}_5\text{H}_5$ , and  $\text{SF}_4 \cdot 8\text{NC}_5\text{H}_5$  adducts at  $-78^\circ\text{C}$ .<sup>[42]</sup> A matrix-isolation infrared spectroscopy (IR) study claimed  $\text{SF}_4$  to form adducts with  $\text{NH}_3$ ,  $\text{NC}_5\text{H}_5$ , and  $\text{CH}_3\text{CN}$  as evidenced by shifts in the IR bands.<sup>[43]</sup> However, due to

severe overlap of many of the reactant and product bands, definitive identification was not possible.

The first conclusive evidence for formation of a SF<sub>4</sub>·nitrogen-base adduct was the synthesis and characterization of SF<sub>4</sub>·N(C<sub>2</sub>H<sub>5</sub>)<sub>3</sub> by X-ray crystallography, LT Raman spectroscopy and <sup>19</sup>F NMR spectroscopy.<sup>[44]</sup> The X-ray crystal structure contained an S---N distance of 2.3844(19) Å. Other adducts between SF<sub>4</sub> and nitrogen bases including pyridine and pyridine derivatives have been synthesized and characterized in the solid state, each of which are stable towards dissociation below -45 °C.<sup>[45]</sup> These X-ray crystal structures exhibited weak interactions between the sulfur and nitrogen atoms with S---N distances ranging from 2.141(2)–2.514(2) Å. Shifts in the characteristic Raman bands of SF<sub>4</sub> and nitrogen bases allowed for the donor strengths of each base to be assessed. It was found that the stronger bases showed larger decreases in the equatorial S–F stretching frequency of SF<sub>4</sub>.

Studies of these Lewis acid-base adducts between SF<sub>4</sub> and nitrogen-bases showed the adducts to be easily be solvolyzed by HF. The X-ray crystal structures of these solvolysis products showed interesting bonding motifs where the nitrogen bases were protonated and hydrogen-bonded to a fluoride anion which was coordinated to a SF<sub>4</sub> (see Figure 1.4).<sup>[46]</sup> In another example, a [HF<sub>2</sub>]<sup>–</sup> anion was shown to accept a hydrogen bond to the protonated nitrogen base as opposed to a fluoride anion.

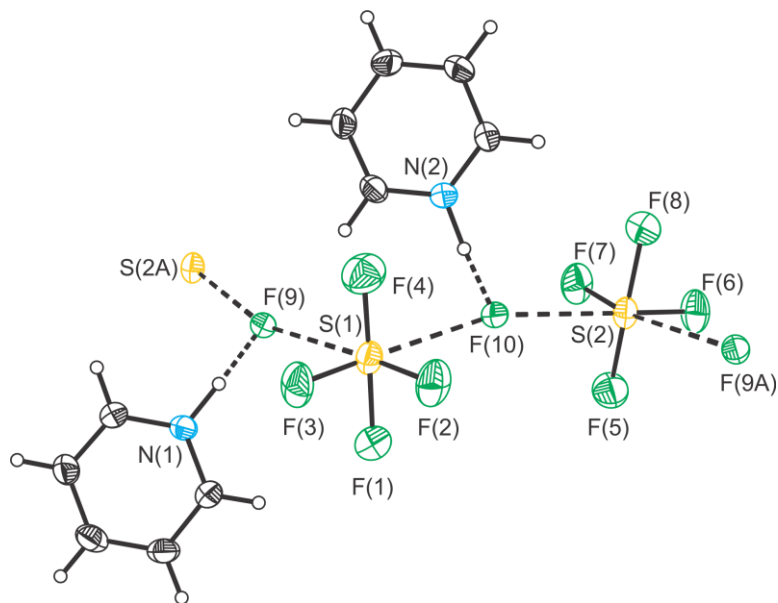

Figure 1.4 Thermal ellipsoid plot of the X-ray crystal structure of  $[\text{HNC}_5\text{H}_5]^+\text{F}^- \cdot \text{SF}_4$  from Ref. 46. Thermal ellipsoids are set at the 50% probability level. The bridging interaction between the fluoride and  $\text{SF}_4$ ,  $\text{F}_4\text{S} \cdots [\text{F}]^-$ , has contacts of 2.6826(9) and 2.7739(9) Å. The  $\text{N}(1)\text{H} \cdots \text{F}(9)$  distance is 2.4367(13) Å.

Sulfur tetrafluoride has also been shown to form Lewis acid-base adducts with oxygen bases via  $\text{S} \cdots \text{O}$  chalcogen bonding interactions. Early NMR spectroscopy studies proposed  $\text{SF}_4$  is not capable of forming adducts with the oxygen-bases tetrahydrofuran (THF) and ethyl acetate since the chemical shift of  $\text{SF}_4$  was unaffected.<sup>[47]</sup> However, LT NMR studies later showed that  $\text{SF}_4$  can form adducts with the solvents diethyl ether and THF since there were changes in  $\delta(^{19}\text{F})$  and a decrease in  $^2J(^{19}\text{F}-^{19}\text{F})$  coupling.<sup>[48]</sup> A matrix-isolation study suggested the 1:1 adduct of  $\text{SF}_4$  and acetone existed based on the appearance of two new bands in the IR spectrum at 680, assigned to  $\nu(\text{S}-\text{F})$ , and  $1706\text{ cm}^{-1}$ , assigned to  $\nu(\text{C}=\text{O})$ .<sup>[49]</sup> Recently, Gerken and co-workers were able to successfully synthesize oxygen-base adducts with  $\text{SF}_4$  and characterize them in the solid state.<sup>[50]</sup> Lewis acid-base adducts of  $\text{SF}_4$  with THF, 1,2-dimethoxyethane, and cyclopentanone were synthesized at low temperatures and characterized by X-ray crystallography and Raman spectroscopy. In

addition, caffeine, containing three Lewis basic sites (i.e., one N and two C=O basic groups), was shown to form an adduct with SF<sub>4</sub> through C=O---S interactions (see Figure 1.4).

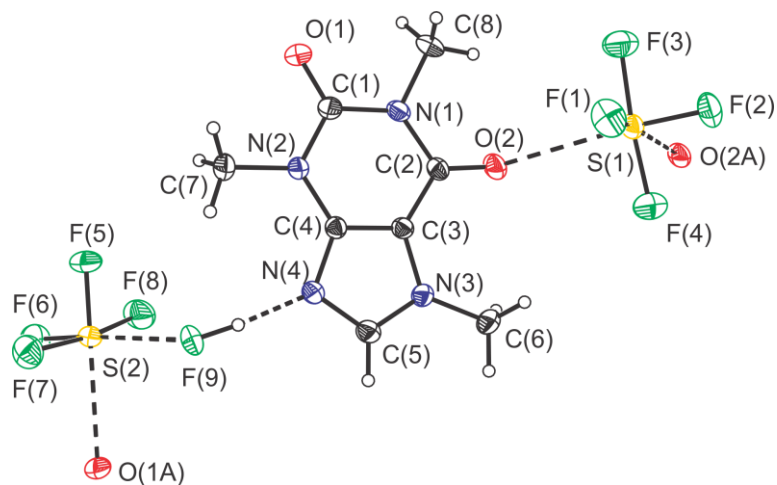

Figure 1.5 Thermal ellipsoid plot of the X-ray crystal structure of C<sub>8</sub>H<sub>10</sub>N<sub>4</sub>O<sub>2</sub>·2SF<sub>4</sub>·HF from Ref. 50. Thermal ellipsoids are set at the 50% probability level. The HF(9) is bridging S(2) of SF<sub>4</sub> (2.7932(15) Å) and the Lewis basic site N(4) of caffeine.

The bonding interactions of this complex, C<sub>8</sub>H<sub>10</sub>N<sub>4</sub>O<sub>2</sub>·2SF<sub>4</sub>·HF (Figure 1.5), showcased SF<sub>4</sub> having a S---F contact with a fluorine atom of HF, which in turn was hydrogen-bonded to the Lewis basic nitrogen site of caffeine. This bonding modality is different from that observed in [HNC<sub>5</sub>H<sub>5</sub>]<sup>+</sup>F<sup>−</sup>·SF<sub>4</sub> where the nitrogen is protonated by HF.

### 1.3 The Chemistry of [SF<sub>3</sub>]<sup>+</sup>

SF<sub>4</sub> has been shown to act as a fluoride-ion donor towards strong Lewis acids such as BF<sub>3</sub>, PF<sub>5</sub>, AsF<sub>5</sub>, and SbF<sub>5</sub> to form the respective [SF<sub>3</sub>]<sup>+</sup> salts (see Equation 1.14).<sup>[21,51]</sup>

The first report of reactions of SF<sub>4</sub> with Lewis acids was by Bartlett and Robinson where it was suggested that these compounds form a donor-acceptor complex, or an adduct (i.e. SF<sub>4</sub>·BF<sub>3</sub>, SF<sub>4</sub>·AsF<sub>5</sub>, SF<sub>4</sub>·SbF<sub>5</sub>). It was later argued that the SF<sub>4</sub>·BF<sub>3</sub> system is not a donor-acceptor complex, but is an ionic species.<sup>[52]</sup> Infrared spectroscopic measurements of the SF<sub>4</sub>·BF<sub>3</sub> adduct were carried out by Seel and Detmer and the presence of a band at 1050 cm<sup>-1</sup> was assigned to [BF<sub>4</sub>]<sup>-</sup>, and two new bands at 908 and 940 cm<sup>-1</sup> were assigned to the [SF<sub>3</sub>]<sup>+</sup> cation.<sup>[53]</sup> A <sup>19</sup>F NMR spectroscopy study of the SF<sub>4</sub>/AsF<sub>5</sub> system by Barr and Dunell reported the presence of two distinct resonances with a 1:2 ratio consistent with the formation of the ionic salt [SF<sub>3</sub>][AsF<sub>6</sub>].<sup>[54]</sup> Solid-state Raman spectroscopy studies were carried out on the SF<sub>4</sub>/MF<sub>5</sub> (M = As and Sb) system and compared to the known K[AsF<sub>6</sub>] and K[SbF<sub>6</sub>] salts showing bands attributable to the respective anions providing further evidence for an ionic species.<sup>[55]</sup> Bands associated with the [SF<sub>3</sub>]<sup>+</sup> in [SF<sub>3</sub>][AsF<sub>6</sub>] were not confidently assigned until Gillespie et al. confirmed its existence in the solid and solution state by Raman (Table 1.1) and NMR spectroscopies, as well as conductivity measurements.<sup>[21]</sup> The <sup>19</sup>F NMR spectra of [SF<sub>3</sub>][AsF<sub>6</sub>] and [SF<sub>3</sub>][SbF<sub>6</sub>] in aHF showed peaks at 30.5 and 27.1 ppm, respectively, attributed to [SF<sub>3</sub>]<sup>+</sup> while the anions, [AsF<sub>6</sub>]<sup>-</sup> and [SbF<sub>6</sub>]<sup>-</sup>, were not observed because of exchange of fluoride with the solvent and quadrupole relaxation of the <sup>75</sup>As (I = 3/2), <sup>121</sup>Sb (I = 5/2), and <sup>123</sup>Sb (I = 7/2) nuclei.

Bartlett and coworkers obtained the X-ray crystal structure of [SF<sub>3</sub>][BF<sub>4</sub>] which crystallized in the *Pnma* space group and showed fluorine bridges between the cation and anion.<sup>[56]</sup> The sulfur center of [SF<sub>3</sub>]<sup>+</sup>, a cation adopting an approximate C<sub>3v</sub> symmetry, contained a coordination number of six with three contacts to fluorine atoms of [BF<sub>4</sub>]<sup>-</sup> (S--F: 2x 2.624(2) and 2.593(3) Å).

Table 1.1 Vibrational frequencies ( $\text{cm}^{-1}$ ) of the  $[\text{SF}_3][\text{AsF}_6]$  salt as reported from reference 21.

Frequency	Assignment
960	} $\nu_1$ and $\nu_3$ $[\text{SF}_3]^+$
945	
926	
686	$\nu_1$ $[\text{AsF}_6]^-$
587	} $\nu_2$ $[\text{AsF}_6]^-$
563	
530	$\nu_2$ $[\text{SF}_3]^+$
411	$\nu_4$ $[\text{SF}_3]^+$
379	$\nu_5$ $[\text{AsF}_6]^-$

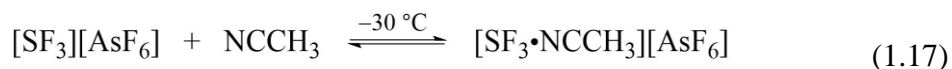

Subsequently, Bartlett prepared the  $[\text{SF}_3][\text{GeF}_5]$  salt by displacement of  $\text{BF}_3$  from  $[\text{SF}_3][\text{BF}_4]$  with  $\text{GeF}_4$  at  $-126^\circ\text{C}$  (Equation 1.15), as well as, the  $[\text{SF}_3]_2[\text{GeF}_6]$  salt by reaction of two equivalents of  $\text{SF}_4$  with  $\text{GeF}_4$  (see Equation 1.16).<sup>[57,58]</sup> These compounds were both characterized by Raman spectroscopy, and crystals of  $[\text{SF}_3]_2[\text{GeF}_6]$  were obtained by sublimation at  $30\text{--}35^\circ\text{C}$ . The crystal structure of  $[\text{SF}_3]_2[\text{GeF}_6]$  contained a  $C_{3v}$ -symmetric cation which exhibits a coordination environment similar to that of  $[\text{SF}_3][\text{BF}_4]$  where the sulfur center has contacts with three fluorine atoms of different  $[\text{GeF}_6]^{2-}$  anions ( $2 \times 2.367(2)$  and  $2.420(1)$  Å).

### 1.3.1 $[\text{SF}_3]^+$ -Nitrogen-Base Adducts

The  $[\text{SF}_3]^+$  cation is highly Lewis acidic and has been found to form adducts with nitrogen bases including pyridine and acetonitrile via S---N bonding interactions. The first report of a Lewis acid-base adduct claimed the formation of  $[\text{SF}_3 \cdot \text{NCCH}_3]^+$ .<sup>[59]</sup> Fluorine-

19 NMR spectroscopy studies of  $[\text{SF}_3][\text{AsF}_6]$  and  $\text{CH}_3\text{CN}$  in  $\text{SO}_2$  at  $-30\text{ }^\circ\text{C}$  showed a change in chemical shift of  $[\text{SF}_3]^+$  to 17.4 ppm upon addition of  $\text{CH}_3\text{CN}$  compared to  $[\text{SF}_3]^+$  in  $\text{SO}_2$  (30.5 ppm). It was concluded that the 1:1 adduct  $[\text{SF}_3\cdot\text{NCCH}_3][\text{AsF}_6]$  was formed in solution (Equation 1.17). This study also suggested that an equilibrium exists whereby the  $[\text{SF}_3\cdot\text{NCCH}_3][\text{AsF}_6]$  salt slowly dissociates into  $\text{SF}_4$  and the  $\text{AsF}_5\cdot\text{NCCH}_3$  adduct (see Equation 1.18).

Evidence for the  $[\text{SF}_3\cdot(\text{NCCH}_3)_2]^+$  and  $[\text{SF}_3\cdot(\text{NC}_5\text{H}_5)_2]^+$  adducts has been reported based on mass spectrometry studies and ab initio calculations for the reaction enthalpies, bond dissociation energies, and optimized geometries for the adducts.<sup>[60–61]</sup>

Chaudhary has recently synthesized a variety of  $[\text{SF}_3]^+$  adducts with nitrogen bases including pyridine, acetonitrile, and phenanthroline.<sup>[62]</sup> The reactions were carried out at  $-40\text{ }^\circ\text{C}$  in solvents such as  $\text{CH}_3\text{CN}$ ,  $\text{CH}_2\text{Cl}_2$ , and  $\text{SO}_2$  and characterized by Raman spectroscopy and  $^{19}\text{F}$  NMR spectroscopy. The characteristic  $\nu_s(\text{SF}_3)$  bands were shifted to lower frequencies by upwards of  $139\text{ cm}^{-1}$ . The  $^{19}\text{F}$  chemical shifts of the  $[\text{SF}_3\cdot(\text{NCCH}_3)_2]^+$  and  $[\text{SF}_3\cdot(\text{NC}_5\text{H}_5)_2]^+$  cations in  $\text{SO}_2$  were shifted to lower frequencies, between 18.5 and 16.8 ppm, in comparison to the values for  $[\text{SF}_3][\text{MF}_6]$  ( $\text{M} = \text{As}$  or  $\text{Sb}$ ) in  $\text{SO}_2$  (32.9, 31.5 ppm). The X-ray crystal structures of  $[\text{SF}_3\cdot(\text{NCCH}_3)_2][\text{MF}_6]$ ,  $[\text{SF}_3\cdot(\text{NC}_5\text{H}_5)_2][\text{MF}_6]$ , and  $[\text{SF}_3\cdot(\text{phen})][\text{SbF}_6]$  were also obtained ( $\text{M} = \text{As}$  or  $\text{Sb}$ ).

## 1.4 Goals of Present Research

Selective fluorination of organic molecules is currently a very active area of research and can be highly valuable for industries such as the pharmaceutical and agrochemical fields. Finding compounds which can more easily and selectively fluorinate a carbonyl functional group requires a better understanding of the deoxofluorination reaction mechanism. The primary goal of this thesis is to explore the Lewis acid-base interactions between  $[\text{SF}_3]^+$ , a highly electrophilic cation believed to be the active species in deoxofluorination reactions, and carbonyl bases. One of the proposed intermediates in deoxofluorination reactions is the  $[\text{R}-\text{O}-\text{SF}_3]^+$  cation ( $\text{R}$  = any alkyl substituent), however, it has yet to be isolated in solution or solid states.<sup>[19]</sup> Based on previous studies of the  $[\text{SF}_3 \cdot (\text{nitrogen-base})_x]^+$  adducts,<sup>[62]</sup> the  $[\text{SF}_3 \cdot (\text{oxygen-base})_x]^+$  ( $x = 1$  or  $2$ ) adducts are believed to be stable at low temperatures ( $< -45^\circ\text{C}$ ), and so the use of LT Raman spectroscopy and  $^{19}\text{F}$  and  $^1\text{H}$  NMR spectroscopy will be used to study these systems in the solution and solid states. In addition, reactions of  $[\text{SF}_3][\text{AsF}_6]$  with ketones and aldehydes in aHF will be carried out at low temperatures in an attempt to shed light on possible intermediates in deoxofluorination reactions.

Sulfur tetrafluoride, a well-known deoxofluorinating agent, has been shown to form Lewis acid-base adducts with ketones.<sup>[50]</sup> This thesis looks to expand the scope of these reactions to include acetone, the simplest aliphatic ketone, and 2-adamantanone, a bulky polycyclic ketone. Like the  $\text{SF}_4 \cdot (\text{O}=\text{C}_5\text{H}_8)_2$  adduct previously studied, the reactions between  $\text{SF}_4$  and acetone, and  $\text{SF}_4$  and 2-adamantanone, will be carried out at low temperatures. X-ray crystallography, together with LT Raman spectroscopy, will be used

to characterize these compounds. Specialized low-temperature mounting techniques will be required when handling these highly temperature and moisture sensitive adducts.

The overall goal of this thesis is to explore the Lewis acid-base interactions between organic carbonyl compounds and Lewis acids such as  $\text{SF}_4$  and the  $[\text{SF}_3][\text{AsF}_6]$  salt, as well as, possible side-products present in these reactions. Different solvents and varying temperatures will be used to carry out these reactions. By using low-temperature techniques to synthesize and characterize these compounds, in conjunction with quantum-chemical calculations, insight into the currently speculated mechanisms of deoxofluorination reactions will be explored.

## 2. Experimental

*CAUTION! Anhydrous HF (aHF) is extremely toxic and corrosive. Exposure can cause severe burns and cause irreparable damage if contact with the skin occurs. It should be handled with extreme care. For the risk and treatments of HF burns the literature should be consulted.<sup>[1]</sup>*

### 2.1 General Methods

The chemistry presented in this thesis is highly temperature- and moisture-sensitive requiring strictly anhydrous conditions. All reactions were carried out under rigorously dried and inert atmospheres using glass and metal vacuum lines, and a nitrogen-atmosphere dry box (Omni Lab, Vacuum Atmospheres). Nitrogen (99.99%, Praxair) was passed through a column containing anhydrous calcium sulfate (cobalt chloride indicator) and activated 4 Å molecular sieves. Edwards two-stage direct-drive RV8 vacuum pumps were used for the metal and glass vacuum lines, and the antechambers of the glove box. The vacuum on the glass and metal lines was approximately  $10^{-3}$  Torr and  $10^{-2}$  Torr, respectively, and were verified by a mercury McLeod gauge (Labconco).

Pyrex-glass vacuum lines equipped with grease-free 6-mm J. Young glass stopcocks with PTFE (polytetrafluoroethylene) barrels were used to manipulate non-corrosive volatiles which do not react with glass (see Figure 2.1). Heise gauges (model CC, 0-1000 mmHg, beryllium/copper Bourdon tube, Dresser Instruments) were used to measure pressures inside the glass manifold. The final vacuum was monitored by Varian model 801 thermocouple gauges connected to the vacuum lines between the liquid nitrogen traps and the vacuum pumps.

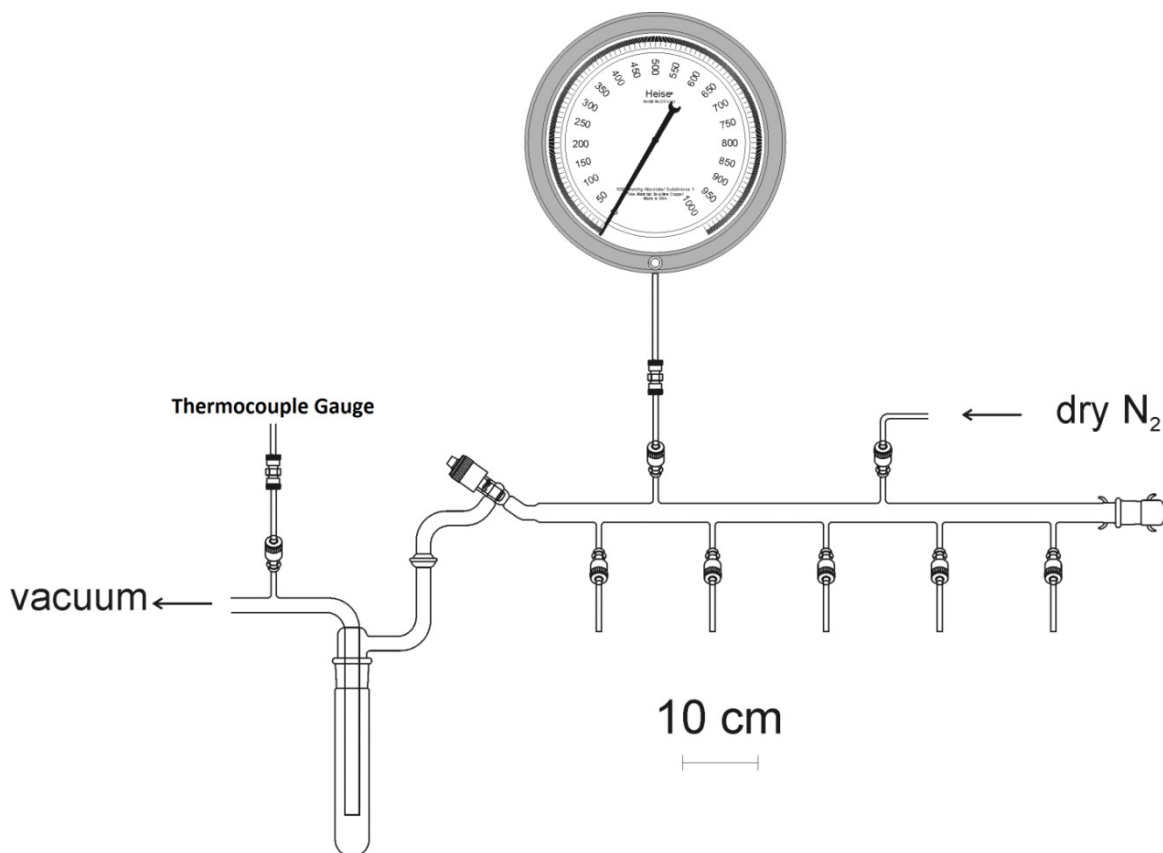

Figure 2.1 Glass vacuum line system equipped with J. Young PTFE/glass stopcocks, a Heise and thermocouple gauge, and vacuum/nitrogen manifolds (Adapted from Jared Nieboer's M.Sc. Thesis, Ref. 2).

Work involving volatile and corrosive fluorides that react with glass (e.g.,  $\text{SF}_4$ ) was carried out on a metal vacuum line (see Figure 2.2) constructed primarily from 316 stainless steel and nickel along with 316 stainless steel valves (Autoclave Engineers, Inc.). PTFE tube fitting connectors (Swagelok) were used to connect  $\frac{1}{4}$ -in. o.d. FEP (Perfluorinated Ethylene Propylene co-polymer) reactors to the metal line. Three vacuum pumps were connected to the metal line: two pumps for fine vacuum connected to small towers of activated charcoal; and one roughing pump connected to a fluoride/fluorine trap consisting of a stainless-steel cylinder (75-cm length, 17-cm outer diameter) packed with soda lime absorbent (EMD, 4 mesh). The fine vacuum pumps provided high vacuum to each

29

Most synthetic work was carried out in reactors constructed from lengths of 1/4-in. o.d. FEP tubing which were heat-sealed at one end and heat-flared (45° SAE) at the other. The tubing was connected to Kel-F (chlorotrifluoroethylene polymer) valves, encased in aluminum housings, using brass (45° SAE) flared nuts (Figure 2.3). All vessels were then connected to a glass vacuum line using 1/4-in. stainless steel Swagelok Ultratorr unions fitted with Viton elastomer O-rings and were rigorously dried by pumping for a minimum of 6 h under dynamic vacuum. The FEP vessels were then connected to the metal vacuum line and passivated with ca. 1000 Torr of F<sub>2</sub> for ca. 12 h. Passivated vessels were evacuated under dynamic vacuum to remove all volatile impurities and back-filled with dry N<sub>2</sub> (ca. 900 Torr) prior to use. Connections made to a glass vacuum line were dried under dynamic vacuum for several hours. All connections to vacuum lines were made using thick-walled 1/4-in. FEP tubing in conjunction with either a 1/4-in. Teflon Swagelok connector outfitted with Teflon compression fittings (front and back ferrules), used on the metal line, or 1/4-in. stainless steel Swagelok Ultra-Torr connectors outfitted with stainless steel compression fittings and Viton elastomer O-rings, used on the glass lines.

Reactions intended for characterization by NMR spectroscopy were performed in reactors crafted from straightened and sealed 4-mm o.d. FEP tubing that was joined to a short, flared 1/4-in. FEP connecting piece. After the contents of the sample were prepared, the 4-mm tube was sealed using a heat gun while the sample was cooled with liquid nitrogen (−196 °C) and placed under dynamic vacuum. This sealed 4-mm tube could then be inserted into a thin-walled 5-mm glass NMR tube before being lowered into the NMR magnet for characterization.

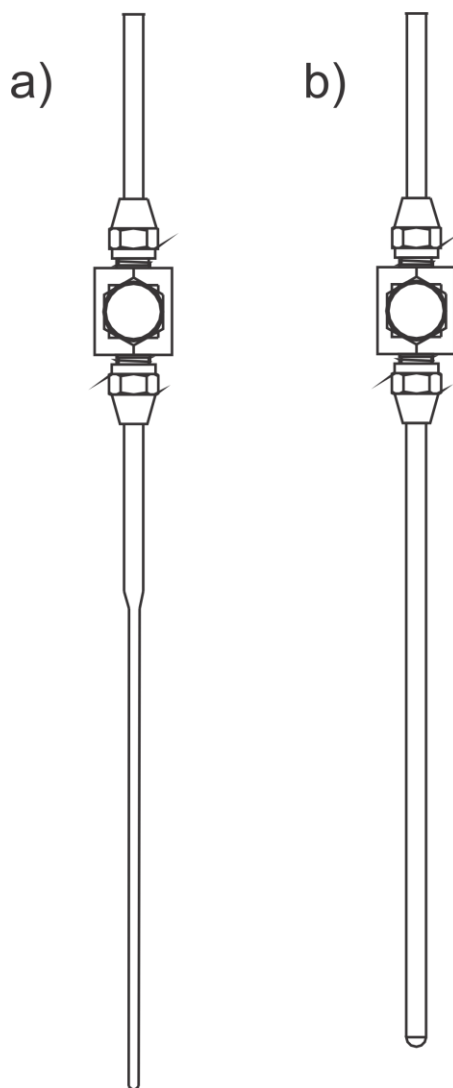

Figure 2.3 Diagrams of (a) a 1/4-in. o.d. and (b) 4-mm o.d. FEP reactor fitted with a Kel-F valve. (from Jared Nieboer's M.Sc. thesis, Ref. 2).

## 2.2 Preparation and Purification of Starting Materials

### 2.2.1 Sources and Purification of N<sub>2</sub> and F<sub>2</sub>

Nitrogen gas (99.99%, Praxair) was dried by passing it through a cartridge of drierite and molecular sieves prior to use. Technical grade fluorine gas (Air Products, >98%) was used without further purification.

## 2.2.2 Solvent Purification; Anhydrous HF (aHF), SO<sub>2</sub>, CH<sub>2</sub>Cl<sub>2</sub>, and CFCl<sub>3</sub>

(i) *aHF*: Anhydrous hydrogen fluoride (Air Products) was stored at room temperature in a nickel storage vessel equipped with a monel (Autoclave Engineers) valve. Hydrogen fluoride was pre-dried with fluorine gas in a ¾-in. o.d. FEP vessel equipped with a stainless-steel valve. The vessel was evacuated and backfilled with approximately 900 Torr of pure fluorine gas. The vessel was agitated periodically for two weeks. After agitating the vessel over a period of two weeks, the HF was vacuum distilled onto potassium hexafluoro-nickelate(IV) in a ¾-in o.d. FEP vessel (see Figure 2.4), equipped with a stainless steel valve, and backfilled with ca. 900 Torr nitrogen. Figure 2.4 shows the distillation setup used to transfer HF from the ¾-in. o.d. FEP vessel to reaction vessels by vacuum distillation on the metal vacuum line through a FEP T-piece FEP connection.

(ii) *SO<sub>2</sub>*: Sulfur dioxide (Matheson Gas Products Canada) was vacuum distilled from a cylinder onto CaH<sub>2</sub> in a dried, glass storage bulb equipped with a Teflon J. Young stopcock.

(iii) *CH<sub>2</sub>Cl<sub>2</sub>*: Dichloromethane was dispensed by an MBraun dry solvent system and then vacuum distilled onto freshly activated 4 Å molecular sieves in a dry Pyrex glass bulb fitted with a J. Young PTFE stopcock after being degassed by the freeze-pump-thaw method.

(iv) *CFCl<sub>3</sub>*: Trichlorofluoromethane was vacuum distilled onto calcium hydride, and vacuum distilled into a dry, evacuated flask with a J. Young PTFE stopcock.

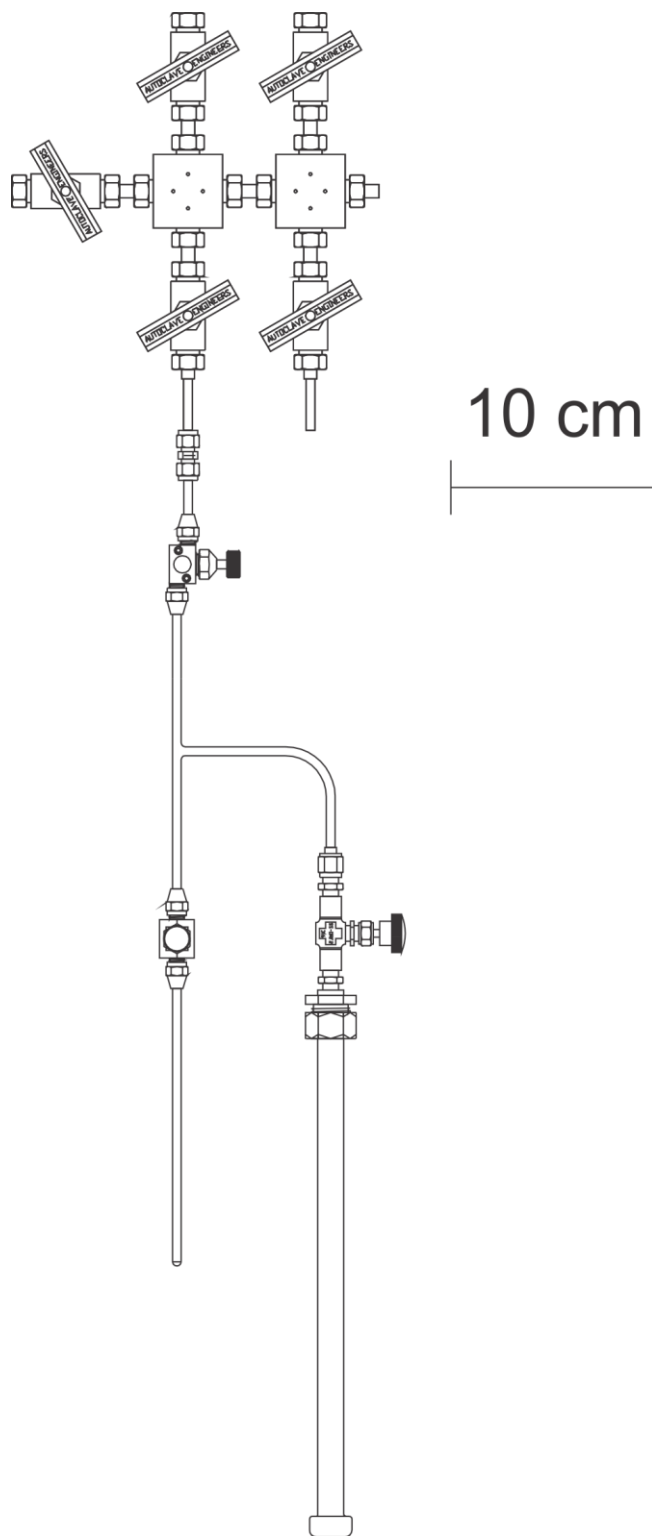

Figure 2.4 A 3/4-in. o.d. FEP vessel equipped with a stainless steel valve and a FEP T-piece connection for the distillation of HF into reactors. (from Jared Nieboer's M.Sc. thesis, Ref. 2).

### 2.2.3 Purification of Oxygen-Bases

(i) *Acetone* ( $O=C(CH_3)_2$ ): Acetone (Sigma-Aldrich, 99.5%) was stored over  $B_2O_3$  in a dried, glass bulb with a J. Young PTFE stopcock.

(ii) *Cyclopentanone* ( $O=C_5H_8$ ): Cyclopentanone (BDH/VWR, 99%) was stored in a dry, glass bulb with a J. Young PTFE stopcock and used as is.

(iii) *2-Adamantanone* ( $O=C_{10}H_{14}$ ): 2-Adamantanone (Sigma-Aldrich, 99%) was stored in a nitrogen-atmosphere dry box and used as received.

### 2.2.4 Synthesis and Purification of $SF_4$ , $SbF_3$ and $AsF_5$

Sulfur tetrafluoride (Ozark-Mahoning Co.) was purified by passing the gas through a U-trap containing activated charcoal, removing any trace amounts of  $S_2F_{10}$  which would interfere with reactions. The  $SF_4$  did contain trace amounts of thionyl fluoride ( $SOF_2$ ) and sulfur hexafluoride ( $SF_6$ ), however, these were assumed not to interfere with any chemistry. The  $SF_4$  was stored in a stainless steel cylinder fitted with a stainless steel valve.

Antimony trifluoride,  $SbF_3$  (Ozark Fluorine Specialities), was sublimed under vacuum and transferred into a storage vessel in a nitrogen-atmosphere dry box.

Arsenic pentafluoride,  $AsF_5$ , was prepared according to the literature procedure and stored in a nickel reactor with a monel (Autoclave Engineers) valve.<sup>[3]</sup>  $AsF_3$  was dried over NaF for 24 h to remove any trace amounts of HF which was subsequently transferred to a 3/4-in. o.d. FEP reactor and directly fluorinated with an excess of  $F_2$  to yield hydrogen fluoride-free  $AsF_5$ .

### 2.2.5 Synthesis of $[\text{SF}_3][\text{AsF}_6]$

The  $[\text{SF}_3][\text{AsF}_6]$  salt was prepared according to the literature method.<sup>[4]</sup> On a steel vacuum line,  $\text{AsF}_5$  (a total of 1658 Torr was added inside the metal vacuum line of 0.01953 mL of volume, 1.77 mmol) was vacuum distilled into a 1/4-in. o.d. FEP reactor and approximately a 1.6-fold excess of  $\text{SF}_4$  (a total of 2737 Torr was added inside the metal vacuum line of 0.01953 mL of volume, 2.92 mmol) was vacuum distilled into the same reactor at  $-196\text{ }^\circ\text{C}$ . The reaction was carried out at  $-78\text{ }^\circ\text{C}$  and then slowly warmed to  $-38\text{ }^\circ\text{C}$  while constantly being agitated to ensure the reaction went to completion. A white powder appeared and the excess  $\text{SF}_4$  was removed by pumping on the solid at RT. The purity of the  $[\text{SF}_3][\text{AsF}_6]$  (0.49 g, 1.76 mmol) was confirmed by Raman spectroscopy. This salt was then stored in a nitrogen-atmosphere dry box until further needed.

## 2.3 Reactions of $\text{SF}_4$ with Ketones

### 2.3.1 Reaction of $\text{SF}_4$ with 2-Adamantanone

Approximately 0.020 g (0.13 mmol) of 2-adamantanone was transferred into a 1/4-in. o.d. FEP reactor in a dry box. Sulfur tetrafluoride (a total of 1624 Torr was added inside the metal vacuum line of 0.01953 mL of volume, 1.74 mmol) was distilled upon the solid at  $-196\text{ }^\circ\text{C}$  on a metal vacuum line. The mixture was warmed to  $-90\text{ }^\circ\text{C}$  where the 2-adamantanone was attempted to be dissolved in the  $\text{SF}_4$ . At  $-67\text{ }^\circ\text{C}$  the white powder was dissolved by constant agitation and a clear, colourless solution remained. Slow cooling to approximately  $-75\text{ }^\circ\text{C}$  resulted in the formation of a fine suspension. This powder was characterized by Raman spectroscopy at  $-90\text{ }^\circ\text{C}$ , however, no signs of adduct formation were observed as only signals of reactants were detected. The excess  $\text{SF}_4$  was pumped off

at  $-65\text{ }^{\circ}\text{C}$  through a FEP U-trap under dynamic vacuum at  $-196\text{ }^{\circ}\text{C}$ . However, after removing approximately half of the liquid a white solid appeared on the walls of the reactor. The FEP reactor was back-filled with  $\text{N}_2$ , redissolved in the  $\text{SF}_4$ , and cooled to  $-75\text{ }^{\circ}\text{C}$  where signs of a white solid appeared. The reactor was left in a cryobath at  $-78\text{ }^{\circ}\text{C}$  for approximately 3 weeks, whereby clear, colourless crystals were formed halfway up the walls of the reactor. Remaining  $\text{SF}_4$  was removed under similar conditions described above and the crystals were isolated from the reaction vessel and mounted on the X-ray diffractometer using low-temperature mounting techniques. A single crystal was isolated and shown to be  $\text{SF}_4 \cdot (\text{O}=\text{C}_{10}\text{H}_{14}) \cdot (\text{HF})$ .

## **2.3.2 Reactions of $\text{SF}_4$ with Acetone**

### **2.3.2.1 Reaction of $\text{SF}_4$ with One Equivalent of Acetone**

Acetone (0.077 g, 1.3 mmol) was distilled into a 1/4-in. o.d. FEP reactor on a glass vacuum line at  $-196\text{ }^{\circ}\text{C}$ . The  $\text{SF}_4$  (a total of 1366 Torr was added inside the metal vacuum line of 0.01953 mL of volume, 1.46 mmol) was distilled onto the frozen acetone over a metal vacuum line at  $-196\text{ }^{\circ}\text{C}$ . The reaction of  $\text{SF}_4$  with acetone was carried out at  $-91\text{ }^{\circ}\text{C}$  in an ethanol bath and yielded a clear colourless solution. White blocks began to crystallize by slowly cooling the reaction to  $-96\text{ }^{\circ}\text{C}$ . The crystals were collected by pumping on the reaction mixture at  $-100\text{ }^{\circ}\text{C}$  to remove any remaining  $\text{SF}_4$  into a FEP U-trap under dynamic vacuum at  $-196\text{ }^{\circ}\text{C}$ . The crystals were characterized by Raman spectroscopy at  $-110\text{ }^{\circ}\text{C}$ .

In a second attempt to grow crystals of this reaction, acetone (0.020 g, 0.34 mmol) was reacted with slightly more than one equivalent of  $\text{SF}_4$  (0.055 g, 0.51 mmol) at  $-98\text{ }^{\circ}\text{C}$  where a clear, colourless solution was formed. The sample was slowly cooled to  $-106\text{ }^{\circ}\text{C}$

where blocks of clear, colourless crystals were grown. The excess SF<sub>4</sub> was pumped off at −112 °C into a FEP U-trap under dynamic vacuum at −196 °C. The clear, colourless block-like crystals remained and were isolated from the reaction vessel and mounted on the X-ray diffractometer using low-temperature mounting techniques. Handling and growing these crystals proved to be extremely challenging since the crystals would melt upon warming above −106 °C. After attempting to mount multiple crystals, a single crystal was obtained, albeit of poor quality, and unambiguously identified as [SF<sub>4</sub>·O=C(CH<sub>3</sub>)<sub>2</sub>]<sub>2</sub>.

#### **2.3.2.2 Reaction of SF<sub>4</sub> with Two Equivalents of Acetone**

Sulfur tetrafluoride (0.071 g, 0.66 mmol) was distilled into a ¼-in. o.d. FEP reactor on a metal vacuum line at −196 °C. Approximately 0.1 mL (ca. 1.35 mmol) of acetone was distilled into a glass graduated weighing vessel equipped with a J. Young PTFE stopcock over a glass vacuum line, and subsequently distilled onto the frozen SF<sub>4</sub> at −196 °C. The reaction was performed at −90 °C and yielded a clear colourless solution. It was left at this temperature for 30 min before cooling to −116 °C, however, there were no signs of crystal formation. When the sample was cooled to −120 °C the solution began to freeze into an amorphous solid. The solid was characterized by Raman spectroscopy at −110 °C.

#### **2.4 Reactions of [SF<sub>3</sub>][AsF<sub>6</sub>] with Ketones in Solutions**

All reactions carried out were monitored using <sup>19</sup>F and <sup>1</sup>H NMR spectroscopy at −80 °C (acetone solvent) or −70 °C (SO<sub>2</sub> solvent). Each respective sample was first melted at −80 °C, in the case where acetone was the solvent, or −70 °C, in the case where SO<sub>2</sub> was the solvent, using an ethanol bath cooled with liquid nitrogen. Once the sample was fully

melted it was placed in the spectrometer which was pre-cooled to either  $-80\text{ }^{\circ}\text{C}$  (acetone solvent) or  $-70\text{ }^{\circ}\text{C}$  ( $\text{SO}_2$  solvent). Once the data were recorded at this temperature the sample was removed from the spectrometer and immediately placed in a pre-cooled ethanol bath set to the desired temperature where it was allowed to warm for a well-defined period of time. The sample was removed from the bath and immediately placed back in the spectrometer which remained at the set temperature ( $-80\text{ }^{\circ}\text{C}$  for acetone solutions;  $-70\text{ }^{\circ}\text{C}$  for  $\text{SO}_2$  solutions). This process was repeated for each temperature. The internal temperature of the reaction mixture was never precisely known as only the temperature of the ethanol bath was measured.

#### **2.4.1 Reaction of $[\text{SF}_3][\text{AsF}_6]$ with Acetone**

##### **2.4.1.1 Reaction of $[\text{SF}_3][\text{AsF}_6]$ with Excess Acetone**

$[\text{SF}_3][\text{AsF}_6]$  (0.012 g, 0.043 mmol) was loaded into a 4-mm FEP reactor in a nitrogen-atmosphere dry box. An excess of acetone (ca. 0.3 mL, 4 mmol) was distilled onto the  $[\text{SF}_3][\text{AsF}_6]$  at  $-196\text{ }^{\circ}\text{C}$  which was then heat sealed. The reaction was slowly warmed to  $-80\text{ }^{\circ}\text{C}$  where the  $[\text{SF}_3][\text{AsF}_6]$  dissolved in acetone. The contents of the reaction were warmed to variable temperatures for well defined time periods ( $-80\text{ }^{\circ}\text{C}$ ,  $-60\text{ }^{\circ}\text{C}$ ,  $-40\text{ }^{\circ}\text{C}$ ,  $-20\text{ }^{\circ}\text{C}$ , and RT) and probed using  $^{19}\text{F}$  and  $^1\text{H}$  NMR spectroscopy at  $-80\text{ }^{\circ}\text{C}$ .

##### **2.4.1.2 Reaction of $[\text{SF}_3][\text{AsF}_6]$ with Three Equivalents of Acetone**

$[\text{SF}_3][\text{AsF}_6]$  (0.055 g, 0.20 mmol) was loaded into a 4-mm FEP reactor in a nitrogen-atmosphere dry box. The reactor was connected to a glass vacuum line where an excess of  $\text{SO}_2$  (ca. 0.5 mL) solvent was distilled onto the  $[\text{SF}_3][\text{AsF}_6]$  and yielding a clear, colourless solution at RT. Approximately three molar equivalents of acetone (0.035 g, 0.61

mmol) were distilled into a glass graduated weighing vessel equipped with a J. Young PTFE stopcock and subsequently distilled onto the  $[\text{SF}_3][\text{AsF}_6]/\text{SO}_2$  at  $-196\text{ }^\circ\text{C}$ . The reactor was heat sealed under dynamic vacuum and slowly warmed to  $-70\text{ }^\circ\text{C}$  where acetone was allowed to react with the  $[\text{SF}_3][\text{AsF}_6]$ . The contents of the reaction were characterized using  $^{19}\text{F}$  and  $^1\text{H}$  NMR spectroscopy at  $-70\text{ }^\circ\text{C}$  after allowing the reaction to warm to  $-65\text{ }^\circ\text{C}$ ,  $-40\text{ }^\circ\text{C}$ ,  $-20\text{ }^\circ\text{C}$ , RT for 2 min, and RT for 10 min.

#### **2.4.1.3 Reaction of $[\text{SF}_3][\text{AsF}_6]$ with Two Equivalents of Acetone**

$[\text{SF}_3][\text{AsF}_6]$  (0.015 g, 0.054 mmol) was loaded into a 4-mm FEP reactor in a nitrogen-atmosphere dry box. The reactor was connected to a glass vacuum line where an excess of  $\text{SO}_2$  (ca. 0.4 mL) solvent was distilled onto the  $[\text{SF}_3][\text{AsF}_6]$  giving a clear, colourless solution at RT. Approximately 2.6 molar equivalents of acetone (0.0078 g, 0.14 mmol) was distilled into a glass graduated weighing vessel equipped with a J. Young PTFE stopcock and subsequently distilled onto the  $[\text{SF}_3][\text{AsF}_6]/\text{SO}_2$  at  $-196\text{ }^\circ\text{C}$ . The reactor was heat sealed under dynamic vacuum and slowly warmed to  $-70\text{ }^\circ\text{C}$  where the acetone was allowed to react with the  $[\text{SF}_3][\text{AsF}_6]$ . The contents of the reaction were characterized using  $^{19}\text{F}$  and  $^1\text{H}$  NMR spectroscopy at  $-70\text{ }^\circ\text{C}$  after allowing to warm to  $-60\text{ }^\circ\text{C}$ ,  $-45\text{ }^\circ\text{C}$ ,  $-40\text{ }^\circ\text{C}$ ,  $-35\text{ }^\circ\text{C}$ , and RT for 5 min.

#### **2.4.1.4 Reaction of $[\text{SF}_3][\text{AsF}_6]$ with One Equivalent of Acetone**

$[\text{SF}_3][\text{AsF}_6]$  (0.018 g, 0.065 mmol) was loaded into a 4-mm FEP reactor in a nitrogen-atmosphere dry box. The reactor was connected to a glass vacuum line where an excess of  $\text{SO}_2$  (ca. 0.4 mL) solvent was distilled onto the  $[\text{SF}_3][\text{AsF}_6]$  and dissolved at RT

to give a clear, colourless solution. Approximately one molar equivalent of acetone (0.0039 g, 0.068 mmol) was distilled into a glass graduated weighing vessel equipped with a J. Young PTFE stopcock and subsequently distilled onto the  $[\text{SF}_3][\text{AsF}_6]/\text{SO}_2$  at  $-196\text{ }^\circ\text{C}$ . The reactor was heat sealed under dynamic vacuum and slowly warmed to  $-70\text{ }^\circ\text{C}$  where the acetone was allowed to react with the  $[\text{SF}_3][\text{AsF}_6]$ . The contents of the reaction were characterized using  $^{19}\text{F}$  and  $^1\text{H}$  NMR spectroscopy at  $-70\text{ }^\circ\text{C}$  after allowing to warm to  $-50\text{ }^\circ\text{C}$ ,  $-45\text{ }^\circ\text{C}$ ,  $-38\text{ }^\circ\text{C}$ ,  $-21\text{ }^\circ\text{C}$ ,  $-13\text{ }^\circ\text{C}$ , and RT for 45 min.

## **2.4.2 Reaction of $[\text{SF}_3][\text{AsF}_6]$ with Cyclopentanone**

### **2.4.2.1 Reaction of $[\text{SF}_3][\text{AsF}_6]$ with Two Equivalents of Cyclopentanone**

$[\text{SF}_3][\text{AsF}_6]$  (0.019 g, 0.068 mmol) was loaded into a 4-mm FEP reactor in a nitrogen-atmosphere dry box. The reactor was connected to a glass vacuum line where an excess of  $\text{SO}_2$  (ca. 0.5 mL) solvent was distilled onto the  $[\text{SF}_3][\text{AsF}_6]$  and dissolved at RT to give a clear, colourless solution. Slightly more than two molar equivalents (i.e., 2.2 molar equivalents) of cyclopentanone (0.013 g, 0.15 mmol) was distilled into a glass graduated weighing vessel equipped with a J. Young PTFE stopcock and subsequently distilled onto the  $[\text{SF}_3][\text{AsF}_6]/\text{SO}_2$  at  $-196\text{ }^\circ\text{C}$ . The reactor was heat sealed under dynamic vacuum and slowly warmed to  $-70\text{ }^\circ\text{C}$  where cyclopentanone was allowed to react with the  $[\text{SF}_3][\text{AsF}_6]$ . The contents of the reaction were characterized using  $^{19}\text{F}$  and  $^1\text{H}$  NMR spectroscopy at  $-70\text{ }^\circ\text{C}$  after allowing to warm to  $-63\text{ }^\circ\text{C}$ ,  $-35\text{ }^\circ\text{C}$ ,  $-15\text{ }^\circ\text{C}$ , RT for 1 min, RT for 3 min, and RT for 10 min.

#### **2.4.2.2 Reaction of [SF<sub>3</sub>][AsF<sub>6</sub>] with One Equivalent of Cyclopentanone**

[SF<sub>3</sub>][AsF<sub>6</sub>] (0.016 g, 0.058 mmol) was loaded into a 4-mm FEP reactor in a nitrogen-atmosphere dry box. The reactor was connected to a glass vacuum line where an excess of SO<sub>2</sub> (ca. 0.4 mL) solvent was distilled onto the [SF<sub>3</sub>][AsF<sub>6</sub>] and dissolved at RT to give a clear, colourless solution. Slightly more than one molar equivalent (i.e. 1.4 molar equivalents) of cyclopentanone (0.007 g, 0.08 mmol) was distilled into a glass graduated weighing vessel equipped with a J. Young PTFE stopcock and subsequently distilled onto the [SF<sub>3</sub>][AsF<sub>6</sub>]/SO<sub>2</sub> at −196 °C. The reactor was heat sealed under dynamic vacuum and slowly warmed to −70 °C where cyclopentanone was allowed to react with the [SF<sub>3</sub>][AsF<sub>6</sub>]. The contents of the reaction were characterized using <sup>19</sup>F and <sup>1</sup>H NMR spectroscopy at −70 °C after allowing to warm to −70 °C, −45 °C, −21 °C, RT for 2 min, and RT for 70 min.

#### **2.4.3 Reaction of [SF<sub>3</sub>][AsF<sub>6</sub>] with 2-Adamantanone**

##### **2.4.3.1 Reaction of [SF<sub>3</sub>][AsF<sub>6</sub>] with Two Equivalents of 2-Adamantanone**

[SF<sub>3</sub>][AsF<sub>6</sub>] (0.045 g, 0.16 mmol) was loaded into a 4-mm FEP reactor in a nitrogen-atmosphere dry box. The reactor was connected to a glass vacuum line where an excess of SO<sub>2</sub> (ca. 0.5 mL) solvent was distilled onto the [SF<sub>3</sub>][AsF<sub>6</sub>] and dissolved at RT to give a clear, colourless solution. Slightly more than two molar equivalents (i.e., 2.3 molar equivalents) of 2-adamantanone (0.0555 g, 0.369 mmol) was loaded into the reactor in the dry box while the sample remained frozen using a metal Dewar filled with dry 4.5-mm copper-plated spheres that had previously been cooled to ca. −140 °C in the glass cryowell (−196 °C) of the dry box. The reactor was quickly brought out of the dry box and connected to a glass vacuum line where the reactor was heat sealed under dynamic vacuum and slowly

warmed to  $-70\text{ }^{\circ}\text{C}$  where 2-adamantanone was allowed to react with the  $[\text{SF}_3][\text{AsF}_6]$ . A white precipitate appeared upon melting and was required to quickly be warmed to  $-10\text{ }^{\circ}\text{C}$  where it dissolved and was immediately cooled to  $-40\text{ }^{\circ}\text{C}$ . The contents of the reaction were characterized using  $^{19}\text{F}$  and  $^1\text{H}$  NMR spectroscopy at  $-40\text{ }^{\circ}\text{C}$ .

$^1\text{H}$  NMR (ppm from  $\text{Si}(\text{CH}_3)_4$ , in  $\text{SO}_2$ ,  $-40\text{ }^{\circ}\text{C}$ ,  $\omega_0(^1\text{H}) = 300\text{ MHz}$ )

Major Component: 2.87 (s), 2.45 (s), 2.41 (s), 2.28 (s), 2.24 (sh), 2.19 (s).

Minor Component: 4.20 (s), 4.14 (s), 3.92 (s), 3.59 (s), 3.42 (s), 3.29 (sh), 3.25 (s), 2.96 (sh), 2.71 (s), 2.60 (s), 2.07 (s).

#### **2.4.3.2 Reaction of $[\text{SF}_3][\text{AsF}_6]$ with One Equivalent of 2-Adamantanone**

$[\text{SF}_3][\text{AsF}_6]$  (0.018 g, 0.065 mmol) was loaded into a 4-mm FEP reactor in a nitrogen-atmosphere dry box. The reactor was connected to a glass vacuum line where an excess of  $\text{SO}_2$  (ca. 0.4 mL) solvent was distilled onto the  $[\text{SF}_3][\text{AsF}_6]$  and dissolved at RT to give a clear, colourless solution. Slightly more than one molar equivalent of 2-adamantanone (0.0101 g, 0.0672 mmol) was loaded into the reactor in the dry box while the sample remained frozen using a metal Dewar filled with dry 4.5-mm copper-plated spheres that had previously been cooled to ca.  $-140\text{ }^{\circ}\text{C}$  in the glass cryowell ( $-196\text{ }^{\circ}\text{C}$ ) of the dry box. The reactor was quickly brought out of the dry box and connected to a glass vacuum line where the reactor was heat sealed under dynamic vacuum and slowly warmed to  $-70\text{ }^{\circ}\text{C}$  where 2-adamantanone was allowed to react with the  $[\text{SF}_3][\text{AsF}_6]$ . The contents of the reaction were characterized using  $^{19}\text{F}$  and  $^1\text{H}$  NMR spectroscopy at  $-70\text{ }^{\circ}\text{C}$  after allowing to warm to  $-70\text{ }^{\circ}\text{C}$ ,  $-65\text{ }^{\circ}\text{C}$ , RT for 5 min, and RT for 2 h.

$^1\text{H}$  NMR (ppm from  $\text{Si}(\text{CH}_3)_4$ , in  $\text{SO}_2$ ,  $-70\text{ }^{\circ}\text{C}$ ,  $\omega_0(^1\text{H}) = 300\text{ MHz}$ )

Warmed to  $-70\text{ }^{\circ}\text{C}$ :

(s).

Warmed to RT for 2 h:

Major Component: 3.01 (s, br), 2.98 (sh), 2.89 (s), 2.85 (s), 2.75 (sh), 2.73 (s), 2.69 (sh),  
2.58 (s), 2.53 (s), 2.45 (s), 2.41 (sh), 2.18 (s).

Minor Component: 4.35 (s), 4.27 (s, br), 4.00 (s), 3.73 (sh), 3.69 (s), 3.53 (s), 3.48 (br),  
2.37 (sh), 2.34 (sh), 2.28 (s), 2.12 (s), 2.06 (s).

## **2.5 Synthesis of Protonated Ketones**

### **2.5.1 Synthesis of $[\text{HO}=\text{C}_{10}\text{H}_{14}][\text{AsF}_6]$**

$[\text{SF}_3][\text{AsF}_6]$  (0.023 g, 0.083 mmol) was loaded into a 1/4-in. o.d. FEP reactor inside a nitrogen-atmosphere dry box followed by distillation of ca. 0.2 mL of aHF which dissolved the salt at room temperature. 2-Adamantanone ( $\text{O}=\text{C}_{10}\text{H}_{14}$ ) (0.0126 g, 0.0839 mmol) was loaded into the reactor in the dry box while the sample remained frozen using a metal Dewar filled with dry 4.5-mm copper-plated spheres that had previously been cooled to ca.  $-140\text{ }^{\circ}\text{C}$  in the glass cryowell ( $-196\text{ }^{\circ}\text{C}$ ) of the dry box. The reactor was quickly

brought out of the dry box and left to react at  $-78\text{ }^{\circ}\text{C}$  at which point a white solid formed. The reactor was allowed to warm to RT where the solid dissolved and a clear, colourless solution remained. Upon cooling to  $-20\text{ }^{\circ}\text{C}$  white needle-like crystals formed. The reactor was placed under dynamic vacuum at  $-72\text{ }^{\circ}\text{C}$  to remove the aHF solvent and  $\text{SF}_4$  into a FEP U-trap at  $-196\text{ }^{\circ}\text{C}$ . A single crystal was found and characterized by X-ray crystallography, using low-temperature mounting techniques, and was shown to be  $[\text{HO}=\text{C}_{10}\text{H}_{14}][\text{AsF}_6]$ .

### 2.5.2 Synthesis of $[\text{HO}=\text{C}_{10}\text{H}_{14}][\text{SbF}_6]$

$\text{SbF}_3$  (0.077 g, 0.43 mmol) was loaded into a 1/4-in. o.d. FEP reactor in a nitrogen-atmosphere dry box. Approximately 0.2 mL of aHF was distilled onto the  $\text{SbF}_3$  at  $-196\text{ }^{\circ}\text{C}$  and backfilled with 1000 Torr of  $\text{F}_2$ . The reactor was continuously agitated at RT allowing for the dissolution of  $\text{F}_2$  and the subsequent reaction with  $\text{SbF}_3$  to form  $\text{SbF}_5$ , until no solid  $\text{SbF}_3$  was left. The excess fluorine was removed and the reactor filled with 800 Torr of  $\text{N}_2$ . 2-Adamantanone (0.0712 g, 0.474 mmol) was loaded into the reactor in the dry box while the sample remained frozen using a metal Dewar filled with dry 4.5-mm copper-plated spheres that had previously been cooled to ca.  $-140\text{ }^{\circ}\text{C}$  in the glass cryowell ( $-196\text{ }^{\circ}\text{C}$ ) of the dry box. The reactor was quickly brought out of the dry box and left to react at  $-78\text{ }^{\circ}\text{C}$  at which point a white solid formed. The reactor was warmed to RT to dissolve the product, forming a clear, colourless solution, and slowly cooled to  $0\text{ }^{\circ}\text{C}$  for ca. 30 min at which point clear, colourless needles crystallized. The excess aHF was removed under dynamic vacuum at  $-78\text{ }^{\circ}\text{C}$  into a FEP U-trap at  $-196\text{ }^{\circ}\text{C}$ . These crystals were characterized using Raman spectroscopy at  $-100\text{ }^{\circ}\text{C}$ .

### 2.5.3 Synthesis of $[\text{HO}=\text{C}_5\text{H}_8][\text{AsF}_6]$

$[\text{SF}_3][\text{AsF}_6]$  (0.048 g, 0.17 mmol) was loaded into a ¼-in. o.d. FEP reactor in a nitrogen-atmosphere dry box then dissolved in ca. 0.2 mL of anhydrous HF (aHF) at room temperature (RT). Cyclopentanone ( $\text{O}=\text{C}_5\text{H}_8$ ) (0.016 g, 0.19 mmol) was distilled into the reactor at  $-196\text{ }^\circ\text{C}$  from a glass graduated weighing vessel with a J. Young PTFE stopcock. The reaction mixture was warmed to  $-78\text{ }^\circ\text{C}$ . A white powder was present which was dissolved by quickly warming to RT and followed by immediately cooling to  $-69\text{ }^\circ\text{C}$  when white needles crystallized. The reactor was further cooled to  $-78\text{ }^\circ\text{C}$  and aHF and  $\text{SF}_4$  removed under dynamic vacuum into a FEP U-trap at  $-196\text{ }^\circ\text{C}$ . A single crystal was found and characterized by X-ray crystallography, using low-temperature mounting techniques, and was shown to be  $[\text{HO}=\text{C}_5\text{H}_8][\text{AsF}_6]$ .

### 2.5.4 Synthesis of $[\text{HO}=\text{C}_5\text{H}_8][\text{SbF}_6]$

$\text{SbF}_3$  (0.054 g, 0.30 mmol) was loaded into a ¼-in. o.d. FEP reactor in a nitrogen-atmosphere dry box. Approximately 0.2 mL of aHF was distilled onto the  $\text{SbF}_3$  at  $-196\text{ }^\circ\text{C}$  and backfilled with 1000 Torr of  $\text{F}_2$ . The reactor was continuously agitated at RT allowing for the dissolution of  $\text{F}_2$  and the subsequent reaction with  $\text{SbF}_3$  to form  $\text{SbF}_5$ , until no solid  $\text{SbF}_3$  was left. The excess fluorine was removed and the reactor filled with 800 Torr of  $\text{N}_2$ . Cyclopentanone ( $\text{O}=\text{C}_5\text{H}_8$ ) (0.028 g, 0.33 mmol) was distilled onto the HF/ $\text{SbF}_5$  at  $-196\text{ }^\circ\text{C}$  from a glass graduated weighing vessel with a J. Young PTFE stopcock and allowed to react at  $-78\text{ }^\circ\text{C}$  forming a white solid. The reactor was quickly warmed to RT to dissolve the product, forming a clear, colourless solution, and immediately cooled to  $-70\text{ }^\circ\text{C}$  for ca. 30 min at which point clear, colourless needles crystallized. The excess aHF was removed

under dynamic vacuum at  $-78\text{ }^{\circ}\text{C}$  into a FEP U-trap at  $-196\text{ }^{\circ}\text{C}$ . A single-crystal was found and characterized by X-ray crystallography, using low-temperature mounting techniques, and was shown to contain  $[\text{HO}=\text{C}_5\text{H}_8][\text{SbF}_6]$ .

#### 2.5.5 Synthesis of $[\text{HO}=\text{C}(\text{CH}_3)_2][\text{SbF}_6]$

$\text{SbF}_3$  (0.041 g, 0.23 mmol) was loaded into a 1/4-in. o.d. FEP reactor in a nitrogen-atmosphere dry box. Approximately 0.2 mL of aHF was distilled onto the  $\text{SbF}_3$  at  $-196\text{ }^{\circ}\text{C}$  and the reactor was filled with 1000 Torr of  $\text{F}_2$ . The reactor was continuously agitated at RT allowing for the dissolution of  $\text{F}_2$  and the subsequent reaction with  $\text{SbF}_3$  to form  $\text{SbF}_5$ , until no solid  $\text{SbF}_3$  was left. The excess fluorine was removed and the reactor filled with 800 Torr of  $\text{N}_2$ . A slight excess of acetone ( $\text{O}=\text{C}(\text{CH}_3)_2$ ) (0.016 g, 0.28 mmol) was distilled onto the  $\text{HF/SbF}_5$  at  $-196\text{ }^{\circ}\text{C}$  from a glass graduated weighing vessel with a J. Young PTFE stopcock and allowed to react at  $-78\text{ }^{\circ}\text{C}$  forming a white solid. The reactor was quickly warmed to RT to dissolve the product, forming a clear, colourless solution, and immediately cooled to  $-78\text{ }^{\circ}\text{C}$  for ca. 30 min at which point clear, colourless needles crystallized. The excess aHF was removed under dynamic vacuum at  $-78\text{ }^{\circ}\text{C}$  into a FEP U-trap at  $-196\text{ }^{\circ}\text{C}$ . A single crystal was found and characterized by X-ray crystallography, using low-temperature mounting techniques, and was shown to be  $[\text{HO}=\text{C}(\text{CH}_3)_2][\text{SbF}_6]$ .

#### 2.5.6 Synthesis of $[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_2]_3[\text{HO}=\text{C}(\text{CH}_3)_2]_3[\text{SbF}_6]_5\text{F}$

$\text{SbF}_3$  (0.068 g, 0.38 mmol) was loaded into a 1/4-in. o.d. FEP reactor in a nitrogen-atmosphere dry box. Approximately 0.2 mL of aHF was distilled onto the  $\text{SbF}_3$  at  $-196\text{ }^{\circ}\text{C}$  and the reactor was filled with 1000 Torr of  $\text{F}_2$ . The reactor was continuously agitated at

RT allowing for the dissolution of F<sub>2</sub> and the subsequent reaction with SbF<sub>3</sub> to form SbF<sub>5</sub>, until no solid SbF<sub>3</sub> was left. The excess fluorine was removed and the reactor filled with 800 Torr of N<sub>2</sub>. Two molar equivalents of acetone (O=C(CH<sub>3</sub>)<sub>2</sub>) (0.044 g, 0.76 mmol) were distilled onto the HF/SbF<sub>5</sub> at −196 °C from a glass graduated weighing vessel with a J. Young PTFE stopcock and allowed to react at −78 °C forming a white solid. The reactor was quickly warmed to RT to dissolve the product, forming a clear, colourless solution, and immediately cooled to −60 °C for ca. 5 min at which point clear, colourless needles crystallized. The excess aHF was removed under dynamic vacuum at −75 °C into a FEP U-trap at −196 °C. A single crystal was found and characterized by X-ray crystallography, using low-temperature mounting techniques, and was shown to be [H{O=C(CH<sub>3</sub>)<sub>2</sub>}<sub>2</sub>]<sub>3</sub>[HO=C(CH<sub>3</sub>)<sub>2</sub>]<sub>3</sub>[SbF<sub>6</sub>]<sub>5</sub>F.

## 2.6 Synthesis of Protonated Aldehydes

### 2.6.1 Synthesis of [H(O=CHC<sub>6</sub>H<sub>5</sub>)<sub>2</sub>][SbF<sub>6</sub>]

SbF<sub>3</sub> (0.044 g, 0.25 mmol) was loaded into a ¼-in. o.d. FEP reactor in a nitrogen-atmosphere dry box. Approximately 0.2 mL of aHF was distilled onto the SbF<sub>3</sub> at −196 °C and the reactor was filled with 1000 Torr of F<sub>2</sub>. The reactor was continuously agitated at RT and aHF washed up and down the walls to see the reaction to completion forming SbF<sub>5</sub>. The excess fluorine was removed and the reactor filled with 800 Torr of N<sub>2</sub>. Benzaldehyde (O=CHC<sub>6</sub>H<sub>5</sub>) (0.024 g, 0.23 mmol) was distilled onto the HF/SbF<sub>5</sub> at −196 °C from a glass graduated weighing vessel with a J. Young PTFE stopcock and allowed to react at −78 °C forming a faint, clear, yellow solution. A white solid formed at which point the reactor was warmed to −60 °C for no more than 10 s to dissolve the product and then cooled to −78 °C.

Pale red, transparent blocks crystallized and excess aHF was removed at  $-78\text{ }^{\circ}\text{C}$  under dynamic vacuum to a FEP U-trap at  $-196\text{ }^{\circ}\text{C}$ . These crystals were characterized by Raman spectroscopy at  $-100\text{ }^{\circ}\text{C}$ . A single crystal was found and characterized by X-ray crystallography, using low-temperature mounting techniques, and was shown to be the hemiprotonated  $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2][\text{SbF}_6]$ . No signs of the monoprotonated benzaldehyde cation were found.

### 2.6.2 Synthesis of $[\text{H}(\text{O}=\text{CHCH}_3)_2][\text{SbF}_6]$ and $[\text{HO}=\text{CHCH}_3][\text{SbF}_6]$

$\text{SbF}_3$  (0.042 g, 0.24 mmol) was loaded into a 1/4-in. o.d. FEP reactor in a nitrogen-atmosphere dry box. Approximately 0.2 mL of aHF was distilled onto the  $\text{SbF}_3$  at  $-196\text{ }^{\circ}\text{C}$  and the reactor was filled with 1000 Torr of  $\text{F}_2$ . The reactor was continuously agitated at RT and aHF washed up and down the walls to see the reaction to completion forming  $\text{SbF}_5$ . Acetaldehyde ( $\text{O}=\text{CHCH}_3$ ) (0.023 g, 0.52 mmol) was distilled onto the  $\text{HF}/\text{SbF}_5$  at  $-196\text{ }^{\circ}\text{C}$  from a glass graduated weighing vessel with a J. Young PTFE stopcock and upon warming to  $-78\text{ }^{\circ}\text{C}$  a clear colourless solution formed with a white powder in the bottom of the reactor. This was easily dissolved by warming to  $-70\text{ }^{\circ}\text{C}$  and agitating the sample. Crystals were grown by slowly removing aHF at  $-78\text{ }^{\circ}\text{C}$  under dynamic vacuum and after 3 hours colourless needles appeared. A single crystal was found and characterized by X-ray crystallography, using low-temperature mounting techniques, and was shown to be the hemiprotonated  $[\text{H}(\text{O}=\text{CHCH}_3)_2][\text{SbF}_6]$ . No signs of the monoprotonated acetaldehyde were observed.

Following a similar procedure, reaction between acetaldehyde (0.015 g, 0.34 mmol) and  $\text{SbF}_5$  (0.27 mmol) was carried out in approximately 0.2 mL of aHF at  $-75\text{ }^{\circ}\text{C}$  resulting

in a white, crystalline solid. This solid was characterized by Raman spectroscopy at  $-100$  °C. No single crystals suitable for X-ray crystallography were found.

## **2.7 Synthesis of the Adducts of AsF<sub>5</sub> with Ketones**

### **2.7.1 Synthesis of AsF<sub>5</sub>·O=C(CH<sub>3</sub>)<sub>2</sub>**

On a metal vacuum line, AsF<sub>5</sub> (0.046 g, 0.27 mmol) was distilled into a 4-mm FEP reactor at  $-196$  °C. The reactor was connected to a glass vacuum line where an excess of SO<sub>2</sub> (ca. 0.4 mL) was distilled onto the AsF<sub>5</sub> and dissolved at  $-60$  °C to give a clear, colourless solution. Slightly less than one molar equivalent of acetone (0.020 g, 0.24 mmol) was distilled into a glass graduated weighing vessel equipped with a J. Young PTFE stopcock and, subsequently, distilled onto the AsF<sub>5</sub>/SO<sub>2</sub> at  $-196$  °C. A clear, colourless solution was present upon warming the reactor to  $-70$  °C. The reactor was heat sealed under dynamic vacuum and the contents of the reaction were characterized using <sup>19</sup>F and <sup>1</sup>H NMR spectroscopy at  $-70$  °C.

Using the same method, the reaction was also carried out in a ¼-in. o.d. FEP reactor. AsF<sub>5</sub> (0.066 g, 0.39 mmol) was dissolved in SO<sub>2</sub> and acetone (0.025 g, 0.43 mmol) was distilled onto the mixture. The reaction was warmed to  $-70$  °C and a fine, white powder-like suspension crashed out of solution. The solid was dissolved upon agitation and, upon slowly cooling, the white powder reappeared. Crystal growth was attempted by slowly cooling the sample, as well as, slowly removing the SO<sub>2</sub> at  $-70$  °C; however, no evidence for crystal formation appeared. The white solid was characterized by Raman spectroscopy at  $-100$  °C.

### 2.7.2 Synthesis of $\text{AsF}_5 \cdot \text{O}=\text{C}_5\text{H}_8$

A 4-mm FEP reactor was connected to a glass vacuum line where cyclopentanone (0.013 g, 0.15 mmol) was distilled into a glass graduated weighing vessel equipped with a J. Young PTFE stopcock and then into the 4-mm reactor. An excess of  $\text{CH}_2\text{Cl}_2$  (ca. 0.5 mL) was distilled onto the cyclopentanone and dissolved at RT to give a clear, colourless solution. Approximately one molar equivalent of  $\text{AsF}_5$  (total of 145 Torr was added inside the metal vacuum line with a volume of 0.01953 mL, 0.15 mmol) was distilled through a metal vacuum line into the reactor containing cyclopentanone and  $\text{CH}_2\text{Cl}_2$  at  $-196^\circ\text{C}$ . Upon warming the reaction to  $-79^\circ\text{C}$ , a fine white powder was suspended in solution. The  $\text{CH}_2\text{Cl}_2$  was pumped off at  $-70^\circ\text{C}$  into a glass U-trap at  $-196^\circ\text{C}$  until only a white powder remained. This was characterized by Raman spectroscopy at  $-100^\circ\text{C}$  and shown to be  $\text{AsF}_5 \cdot \text{O}=\text{C}_5\text{H}_8$ . An excess of  $\text{SO}_2$  was distilled onto the  $\text{AsF}_5 \cdot \text{O}=\text{C}_5\text{H}_8$  adduct and dissolved at  $-50^\circ\text{C}$ . The reactor was heat sealed under dynamic vacuum and the  $\text{AsF}_5 \cdot \text{O}=\text{C}_5\text{H}_8$  adduct was further characterized using  $^{19}\text{F}$  and  $^1\text{H}$  NMR spectroscopy at  $-70^\circ\text{C}$ .

### 2.7.3 Synthesis of $\text{AsF}_5 \cdot \text{O}=\text{C}_{10}\text{H}_{14}$

2-Adamantanone (0.016 g, 0.11 mmol) was loaded into a 4-mm FEP reactor inside a nitrogen-atmosphere dry box followed by distillation of ca. 0.3 mL of  $\text{SO}_2$  on a glass vacuum line which easily dissolved at RT. One molar equivalent of  $\text{AsF}_5$  (total of 100 Torr was added inside the metal vacuum line with a volume of 0.01953 mL, 0.11 mmol) was distilled through a metal vacuum line into the reactor containing 2-adamantanone and  $\text{SO}_2$  at  $-196^\circ\text{C}$ . A clear, colourless solution was present upon warming the reactor to  $-70^\circ\text{C}$ .

The reactor was heat sealed under dynamic vacuum and the product was characterized using  $^{19}\text{F}$  and  $^1\text{H}$  NMR spectroscopy at  $-70\text{ }^{\circ}\text{C}$  and found to be the  $\text{AsF}_5\cdot\text{O}=\text{C}_{10}\text{H}_{14}$  adduct.

Using a similar method, the reaction was also carried out in a ¼-in. o.d. FEP reactor. 2-Adamantanone (0.019 g, 0.13 mmol) was dissolved in  $\text{CH}_2\text{Cl}_2$  (ca. 0.6 mL) at RT and approximately one equivalent of  $\text{AsF}_5$  (total of 140 Torr was added inside the metal vacuum line with volume of 0.01953 mL, 0.15 mmol) was distilled onto the mixture. The reaction was warmed to  $-80\text{ }^{\circ}\text{C}$  giving a clear, light yellow solution. The  $\text{CH}_2\text{Cl}_2$  was pumped off at  $-70\text{ }^{\circ}\text{C}$  into a glass U-trap at  $-196\text{ }^{\circ}\text{C}$  until a white powder remained. This was characterized by Raman spectroscopy at  $-100\text{ }^{\circ}\text{C}$  and shown to be  $\text{AsF}_5\cdot\text{O}=\text{C}_{10}\text{H}_{14}$ . Crystal growth was attempted, however, no evidence for crystal formation appeared.

## **2.8 Single-Crystal X-ray Diffraction**

### **2.8.1 Low-Temperature Crystal Mounting**

All samples containing thermally unstable and moisture-sensitive crystals were manipulated using a low-temperature crystal-mounting setup, as shown in Figure 2.5. The FEP sample tubes containing the crystals were cut open and manipulated in an aluminum trough, set to the desired temperature, under a stream of dry, cold nitrogen produced by passing dry, gaseous nitrogen through a 5 L Dewar of liquid nitrogen. The temperature of the trough was regulated by adjusting the flow rate of nitrogen passing through the Dewar and was monitored using a copper/constantan thermocouple with a digital readout. Single-crystals were isolated and affixed to a cryo-loop bound to a metallic pin which was magnetically mounted to a wand allowing for easy manipulation of the crystals inside the trough. For the crystals obtained in Chapters 3 and 5, the trough was set to  $-85\text{ }^{\circ}\text{C}$  (with

the exception of  $(\text{SF}_4 \cdot \text{O}=\text{C}(\text{CH}_3)_2)_2$  where the trough was set to  $-110\text{ }^\circ\text{C}$ ) and a perfluorinated polyether oil, Fomblin Z-25 (Ausimont Inc.), was used to affix the crystals to the cryo-loop. The metal goniometer tip containing the crystal was transported to the goniometer using liquid- $\text{N}_2$ -cooled cryo-tongs.

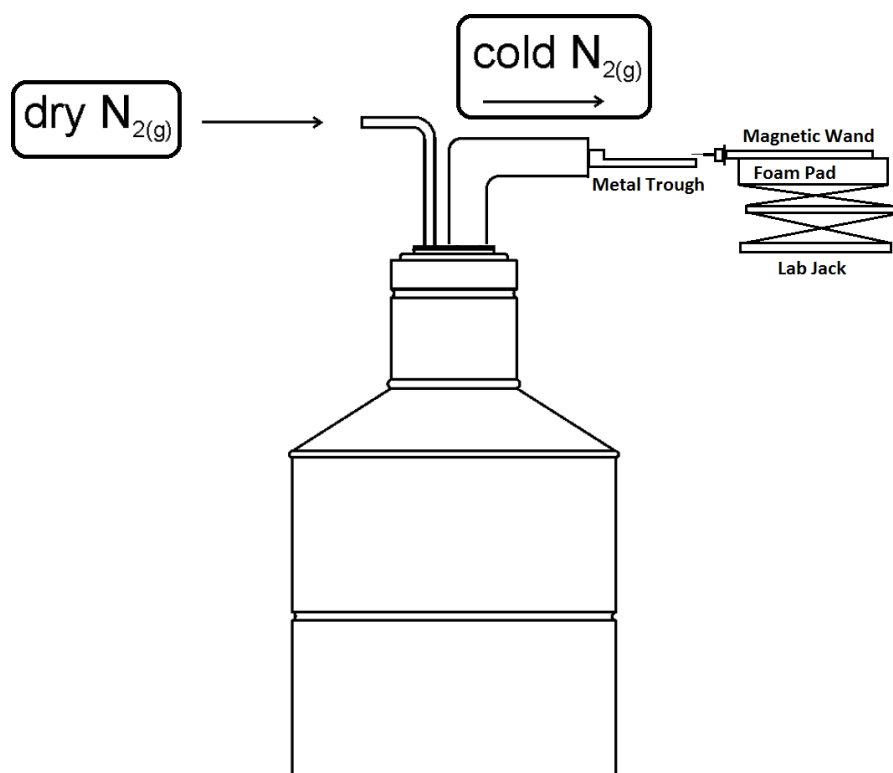

Figure 2.5 Low-temperature crystal-mounting setup, consisting of a 10.5 L Dewar, equipped with a foam stopper, a glass nitrogen inlet, a silvered glass cold nitrogen outlet with an 11 cm long aluminum trough (2 cm o.d.). (Adapted from Jared Nieboer's M.Sc. Thesis, Ref. 2).

## 2.8.2 Data Collection and Reduction

All crystals were centered on a Rigaku SuperNova diffractometer equipped with a Dectris Pilatus 3R 200K-A hybrid-pixel-array detector, a four-circle  $\kappa$  goniometer, and sealed, graphite-monochromated  $\text{MoK}_\alpha$  and  $\text{CuK}_\alpha$  X-ray sources. For

$\text{SF}_4 \cdot (\text{O}=\text{C}_{10}\text{H}_{14}) \cdot (\text{HF})$ ,  $(\text{SF}_4 \cdot \text{O}=\text{C}(\text{CH}_3)_2)_2$ ,  $[\text{HO}=\text{C}_{10}\text{H}_{14}][\text{AsF}_6]$ , and  $[\text{HO}=\text{C}_5\text{H}_8][\text{AsF}_6]$  data were collected using the  $\text{CuK}_\alpha$  source ( $\lambda = 1.54184 \text{ \AA}$ ) at 100 K. For  $[\text{HO}=\text{C}_5\text{H}_8][\text{SbF}_6]$ ,  $[\text{HO}=\text{C}(\text{CH}_3)_2][\text{SbF}_6]$ ,  $[\text{H}(\text{O}=\text{C}(\text{CH}_3)_2)_2]_3[\text{HO}=\text{C}(\text{CH}_3)_2]_3[\text{SbF}_6]_5\text{F}$ ,  $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2][\text{SbF}_6]$ , and  $[\text{H}(\text{O}=\text{CHCH}_3)_2][\text{SbF}_6]$  data were collected using the  $\text{MoK}_\alpha$  source ( $\lambda = 0.71073 \text{ \AA}$ ) at 100 K. The data were processed using CrysAlisPro,<sup>[5]</sup> which applied necessary Lorentz and polarization corrections to the integrated data and scaled the data. A numerical (Gaussian-grid) absorption correction was generated based upon the indexed faces of the crystal.

### 2.8.3 Structure Solution and Refinement

Atom positions were determined using the intrinsic phasing method (ShelXT)<sup>[6]</sup> and were refined using least-squares refinement (ShelXL).<sup>[7]</sup> Structure solution and refinement were performed with the aid of Olex2.<sup>[8]</sup> Non-hydrogen atoms were refined anisotropically and the extinction coefficient was calculated for the crystal structure. If the error in the extinction coefficient was on the same order of magnitude as the extinction coefficient, it was omitted. Recommended weights for the atoms were determined before hydrogen atoms were introduced using a riding model (HFIX). For the crystal structures reported in Chapter 5 (protonated ketones and aldehydes), protons bound to oxygen were found using the Fourier difference map and their positions freely refined. Both residual values,  $R_1$  based on  $F$  and the weighted residual values  $wR_2$  based on  $F^2$ , are available in the structure refinement tables along with the goodness of fit (*Goof*). They represent the following equations:

$$R_1 = \frac{\sum ||F_{obs}| - |F_{calc}||}{\sum F_{obs}}$$

The conventional R-factor based upon the structure factor.

$$wR_2 = \sqrt{\frac{\sum [w(F_{obs}^2 - F_{calc}^2)^2]}{\sum [w(F_{obs}^2)]}}$$

The weighted R-factor based on the square of the structure factors.

$$GooF = \sqrt{\frac{\sum [w(F_{obs}^2 - F_{calc}^2)]}{(n-p)}}$$

The *GooF* is based upon intensity where *n* is the number of reflections and *p* is the number of parameters defined.

## 2.9 Raman Spectroscopy

All Raman spectra were recorded on a Bruker RFS 100 FT Raman spectrometer with a quartz beam splitter, a liquid-nitrogen cooled Ge detector, and R-496 low-temperature accessory. The actual usable Stokes range was from 50 to 3500 cm<sup>-1</sup>. The 1064 nm line of an Nd:YAG laser was used for excitation of the sample. The Raman spectra were recorded with a spectral resolution of 2 cm<sup>-1</sup> using laser powers of 150 or 200 mW. The samples were recorded in Pyrex-glass NMR tubes equipped with a J. Young Valve, and 4-mm and 1/4-in. o.d. FEP reactors. Spectra were visualized and analyzed using *OPUS* 4.2.<sup>[9]</sup>

## 2.10 NMR Spectroscopy

NMR spectra were recorded unlocked on a 300.13 MHz (7.0486 T) Bruker Advance II NMR spectrometer equipped with a BBFO probe which has variable-temperature

capabilities ranging from +150 to -150 °C. *Bruker TopSpin 3.5* was used for data refinement and visualization.<sup>[10]</sup> The Fluorine-19 NMR spectra were externally referenced to neat  $\text{CFCl}_3$  at RT. Proton spectra were externally referenced to neat TMS at RT. Shimming on the NMR samples was performed manually on the most intense signal for all samples. All samples were contained in 4-mm FEP tubes that were inserted into 5-mm thin-walled glass NMR tubes. All  $^{19}\text{F}$  NMR spectra were first obtained with a spectral window of 603.55 ppm (170.45 kHz) centered at -50 ppm, a default pre-scan delay of 6  $\mu\text{s}$ , and a relaxation delay of 1 s. Afterwards, the spectral window was adjusted to include only the signals of interest. The number of FID data points, acquisition time, and number of scans were optimized for each sample to ensure a good signal-to-noise ratio and digital resolution was obtained. In some cases, specifically for the NMR data presented in Chapter 4, the relaxation delay was increased to upwards of 5 s.

## 2.11 Computational Details

All quantum-chemical calculations were performed using the Gaussian 09 program package.<sup>[11]</sup> The X-ray crystal structure was used as a starting geometry, when permitted (i.e., Chapter 5 compounds and the  $(\text{SF}_4 \cdot \text{O}=\text{C}(\text{CH}_3)_2)_2$  dimer in Chapter 3). Density functional theory (DFT) calculations were carried out to optimize the gas-phase geometries of the  $(\text{SF}_4 \cdot \text{O}=\text{C}(\text{CH}_3)_2)_2$  dimer (Chapter 3), proposed intermediates in the deoxy-fluorination reaction (Chapter 4), protonated ketones and aldehydes (Chapter 5), and adducts of  $\text{AsF}_5$  with ketones (Chapter 6). Specifically, the B3LYP/aug-cc-pVTZ level of theory was chosen for all calculations as it provides reliable structural information. Indeed, the PBE1PBE and B3LYP functionals with the 6-311+G(2df,p) and aug-cc-pVTZ basis

sets result in little to no difference in the geometric parameters for the representative test cases of acetone and protonated acetone (see Tables 2.1 and 2.2).

The energy-minimized geometries were used to calculate B3LYP/aug-cc-pVTZ vibrational frequencies along with the IR and Raman intensities. No scaling factors were used on the calculated vibrational frequencies. The experimental vibrational frequencies were best approximated using the B3LYP functional compared to the PBE1PBE functional (Tables 2.3 and 2.4), which further underscores the reliability of the computational approach used in this thesis. The B3LYP/aug-cc-pVTZ combination resulted in real frequencies for all calculated compounds, with the exception of the  $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2]^+$  (Chapter 5) and  $[(\text{CH}_3)_2\text{FCOSF}_2]^+$  (Chapter 4) cations. These two gas-phase geometries consistently converged to stationary points with a small ( $-10\text{ cm}^{-1}$  for  $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2]^+$ ;  $-13\text{ cm}^{-1}$  for  $[(\text{CH}_3)_2\text{FCOSF}_2]^+$ ) imaginary frequency using the aug-cc-pVTZ basis set. These frequencies corresponded to the symmetric rocking of the two benzaldehyde molecules ( $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2]^+$ ) and asymmetric rocking of the fluorocarbenium moiety ( $[(\text{CH}_3)_2\text{CF}]^+$ ) and  $\text{SOF}_2$  moiety of  $[(\text{CH}_3)_2\text{FCOSF}_2]^+$ . The cc-pVTZ basis set was used for  $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2]^+$  which resulted in an energy-minimized geometry with all positive frequencies. This approach is justified since B3LYP with both the aug-cc-pVTZ and cc-pVTZ basis sets shows no difference in the optimized geometrical parameters or vibrational frequencies for the test cases of acetone and protonated acetone. Due to the discrepancy with the crystal structure, in the case of  $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2]^+$ , hemiprotonated benzaldehyde was further probed by adjusting the starting geometry such that the dihedral angle between the benzene rings was  $45^\circ$ ; however, the optimized geometry still resulted in the rings being coplanar. In addition, adjusting the position of the proton in the O–H–O moiety consistently resulted in an asymmetric structure, with different O–H distances. Therefore,

the symmetry observed in the X-ray crystal structure is likely the result of site symmetry in the unit cell.

For the compounds presented in Chapter 5 and Chapter 6, the NBO analyses were performed using the NBO-6.0 program.<sup>[12]</sup> The GaussView program was used to visualize the vibrational displacements and aid in assignments of the bands, and visualize the molecular orbitals.<sup>[13]</sup>

### 3. Lewis Acid-Base Interactions Between SF<sub>4</sub> and Acetone and 2-Adamantanone

#### 3.1 Introduction

Sulfur tetrafluoride is a well-known deoxofluorinating agent used in organic chemistry.<sup>[1]</sup> In such reaction mixtures, the weak Lewis acid SF<sub>4</sub> can interact with a carbonyl functional group through S---O secondary bonding interactions. Early <sup>19</sup>F NMR spectroscopy studies had suggested SF<sub>4</sub> does not form adducts with the oxygen-bases THF and ethyl acetate since the chemical shift of SF<sub>4</sub> was unaffected.<sup>[2]</sup> However, it was later shown at low temperatures, that SF<sub>4</sub> does form adducts with the solvents diethyl ether and THF as evidenced by changes in  $\delta(^{19}\text{F})$  and a decrease in  $^2J(^{19}\text{F}-^{19}\text{F})$  coupling.<sup>[3]</sup> Sass and Ault carried out matrix-isolation studies on the 1:1 adduct of SF<sub>4</sub> and acetone and suggested these compounds form weak S---O bonding interactions based on the presence of two new bands in the IR spectrum at 680, assigned to  $\nu(\text{S}-\text{F})$ , and 1706 cm<sup>-1</sup>, assigned to  $\nu(\text{C}=\text{O})$ .<sup>[4]</sup>

These S---O chalcogen bonding modalities have long been postulated to exist, however, isolating such compounds has proven to be challenging. Only recently have Gerken and co-workers managed to successfully synthesize oxygen-base adducts with SF<sub>4</sub> in the solid state.<sup>[5]</sup> Lewis acid-base adducts of SF<sub>4</sub> and the oxygen-bases THF, 1,2-dimethoxyethane, and cyclopentanone were synthesized at low temperatures and characterized by X-ray crystallography and Raman spectroscopy. Density Functional Theory (DFT) calculations at the B3LYP/aug-cc-pVTZ level of theory were used to determine the optimized gas-phase geometries of these compounds and the calculated vibrational modes were used to aid in the assignments of the Raman bands. In addition, caffeine, containing three Lewis basic sites (i.e., one N and two C=O basic groups), was shown to form an adduct with SF<sub>4</sub> through C=O---S interactions. This complex,

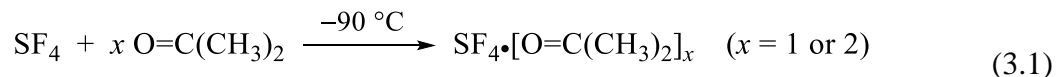

C<sub>8</sub>H<sub>10</sub>N<sub>4</sub>O<sub>2</sub>·2SF<sub>4</sub>·HF, also showcased a unique bonding interaction where the sulfur center of SF<sub>4</sub> had an S---F contact with a fluorine atom of HF, which in turn was hydrogen-bonded to the Lewis basic nitrogen site of caffeine.

Studies of the interactions between SF<sub>4</sub> and nitrogen bases found the resulting adducts to be very air and moisture sensitive. The solvolysis reactions by HF of the adduct between SF<sub>4</sub> and pyridine, as well as pyridine derivatives, were studied by X-ray crystallography and Raman spectroscopy.<sup>[6]</sup> These systems showed unique bonding motifs in the solid state including the F<sub>4</sub>S---N and F<sub>4</sub>S---(F)---HN interactions.

## 3.2 Results and Discussion

### 3.2.1 Synthesis and Properties of [SF<sub>4</sub>·O=C(CH<sub>3</sub>)<sub>2</sub>]<sub>2</sub>, SF<sub>4</sub>·[O=C(CH<sub>3</sub>)<sub>2</sub>]<sub>2</sub>, and SF<sub>4</sub>·(O=C<sub>10</sub>H<sub>14</sub>)·(HF)

The previously synthesized SF<sub>4</sub>·(O=C<sub>5</sub>H<sub>8</sub>)<sub>2</sub> is currently the only example of a Lewis acid-base adduct involving a ketone and SF<sub>4</sub> in the solid state.<sup>[5]</sup> The reactions of acetone, the simplest aliphatic ketone, and 2-adamantanone, a polycyclic ketone, with SF<sub>4</sub> were carried out to further explore the structure and bonding of these Lewis acid-base adducts. Acetone was reacted with slightly more than one equivalent of SF<sub>4</sub>, as well as a 2:1 stoichiometric ratio at −90 °C where the two reagents were miscible and formed clear colourless solutions (see Equation 3.1).

The reaction of SF<sub>4</sub> with one equivalent of acetone yielded white blocks that crystallized by slowly removing any remaining SF<sub>4</sub> under dynamic vacuum at −96 °C. The reaction of SF<sub>4</sub> with two equivalents of acetone was slowly cooled to −116 °C with no signs of crystal

formation. When the sample was cooled to  $-120\text{ }^{\circ}\text{C}$  the solution began to freeze into an amorphous solid. Both solid samples were characterized by LT Raman spectroscopy. In both reactions, no sign of deoxofluorination of the carbonyl group was observed in the Raman spectrum under these conditions ( $T < -90\text{ }^{\circ}\text{C}$ ).

Crystals of the  $[\text{SF}_4 \cdot \text{O}=\text{C}(\text{CH}_3)_2]_2$  adduct suitable for single-crystal X-ray diffraction were obtained from a reaction of acetone with 1.5 equivalents of  $\text{SF}_4$ . This clear, colourless solution was slowly cooled to  $-106\text{ }^{\circ}\text{C}$  where colourless crystals began to form. The excess  $\text{SF}_4$  was removed at  $-112\text{ }^{\circ}\text{C}$  leaving behind clear white crystals. A single crystal suitable for X-ray crystallography was isolated and shown to be the  $[\text{SF}_4 \cdot \text{O}=\text{C}(\text{CH}_3)_2]_2$  dimer (see Section 3.2.2).

An excess of  $\text{SF}_4$  was added to a known amount of 2-adamantanone at  $-90\text{ }^{\circ}\text{C}$ , at which temperature the 2-adamantanone was insoluble. The sample was warmed to  $-67\text{ }^{\circ}\text{C}$  where the white powder dissolved in the  $\text{SF}_4$  forming a clear, colourless solution. Upon slowly cooling to  $-75\text{ }^{\circ}\text{C}$  a white powder began crashing out, which was identified as 2-adamantanone by low-temperature Raman spectroscopy, suggesting that an adduct did not form with  $\text{SF}_4$ . The sample was concentrated by slowly removing approximately half the  $\text{SF}_4$  at  $-60\text{ }^{\circ}\text{C}$ . The white powder was redissolved in  $\text{SF}_4$  and stored in an ethanol bath at  $-75\text{ }^{\circ}\text{C}$ . After two weeks, clear, colourless crystals were observed above the  $\text{SF}_4$  solution. One single crystal was isolated and X-ray crystallography showed this to be  $\text{SF}_4 \cdot (\text{O}=\text{C}_{10}\text{H}_{14}) \cdot (\text{HF})$ . Raman spectroscopy was not used to characterize this serendipitously obtained crystal.

### 3.2.2 X-ray Crystallography of $[\text{SF}_4 \cdot \text{O}=\text{C}(\text{CH}_3)_2]_2$

The crystallographic parameters and details of data collection for  $[\text{SF}_4 \cdot \text{O}=\text{C}(\text{CH}_3)_2]_2$  are given in Table 3.1. The bond lengths and bond angles are listed in Table 3.2. Handling and growing these crystals proved to be extremely challenging since the crystals melted above  $-106\text{ }^\circ\text{C}$ . After attempting to mount multiple crystals, a single crystal was obtained, albeit of poor quality, and unambiguously identified as the  $[\text{SF}_4 \cdot \text{O}=\text{C}(\text{CH}_3)_2]_2$  despite the large  $R_1$  of 7.89%.

Table 3.1 Summary of X-ray Crystal Data and Refinement Results of  $[\text{SF}_4 \cdot \text{O}=\text{C}(\text{CH}_3)_2]_2$ .

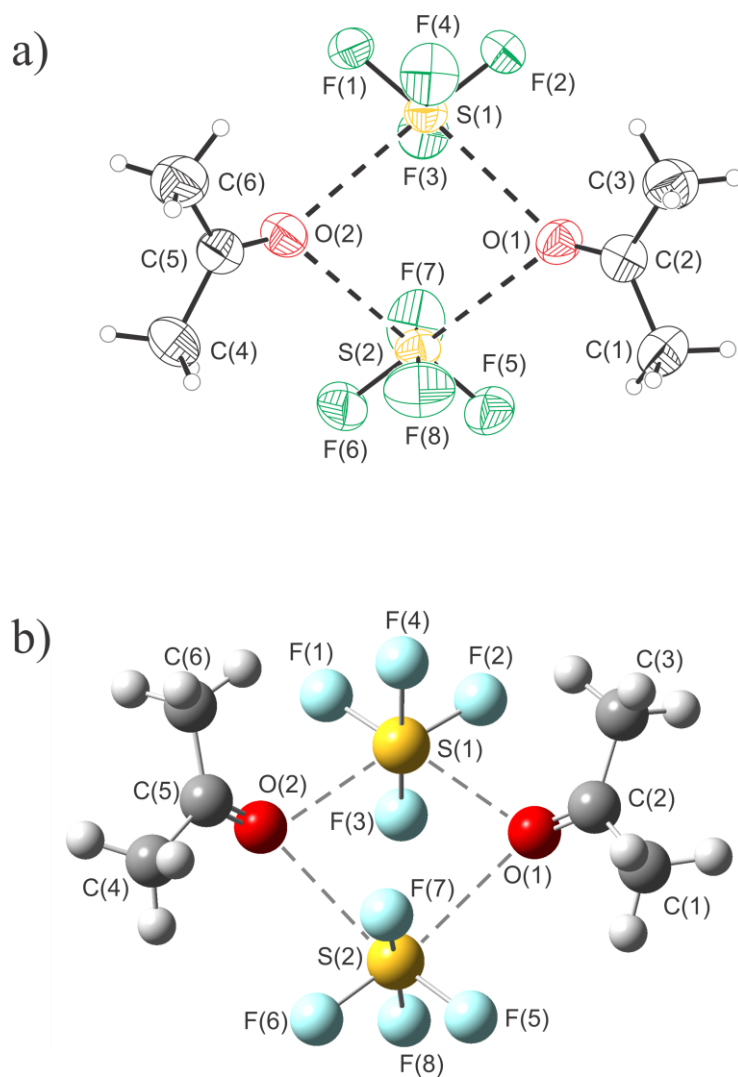

Figure 3.1 a) Thermal ellipsoid plots of  $[\text{SF}_4 \cdot \text{O}=\text{C}(\text{CH}_3)_2]_2$ . Thermal ellipsoids are set at the 50% probability level. b) Geometry-optimized gas-phase structure of  $[\text{SF}_4 \cdot \text{O}=\text{C}(\text{CH}_3)_2]_2$  at the B3LYP/aug-cc-pVTZ level of theory.

The  $[\text{SF}_4 \cdot \text{O}=\text{C}(\text{CH}_3)_2]_2$  adduct crystallized in the  $P\bar{1}$  space group with two acetone molecules and two  $\text{SF}_4$  molecules in the asymmetric unit (Figure 3.1). Each crystallographically unique  $\text{SF}_4$  is coordinated by two bridging acetone molecules through  $\text{S} \cdots \text{O}$  dative bonds forming the  $[\text{SF}_4 \cdot \text{O}=\text{C}(\text{CH}_3)_2]_2$  dimer. The two acetone molecules, essentially eclipsed and in a *syn* conformation, form somewhat stronger chalcogen-bonding interactions with the S(1) center ( $\text{S}(1) \cdots \text{O}(1)$  2.842(2);  $\text{S}(1) \cdots \text{O}(2)$  2.866(2) Å) compared

to the S(2) center (S(2)---O(1) 2.899(2); S(2)---O(2) 2.890(2) Å) of SF<sub>4</sub>. These distances are longer than those reported for previous S(IV)---O adducts, including the (SF<sub>4</sub>·THF)<sub>2</sub> dimer (S---O contacts: 2.7766(17)–2.8022(19) Å), and the SF<sub>4</sub>·(O=C<sub>5</sub>H<sub>8</sub>)<sub>2</sub> adduct (S---O contacts: 2.7952(12) and 2.7880(12) Å).<sup>[5]</sup> This reflects the weaker Lewis basicity of acetone (BF<sub>3</sub> affinity of 76.03±0.21 kJ/mol) compared to THF (BF<sub>3</sub> affinity of 90.40±0.28 kJ/mol).<sup>[7]</sup> As observed for other SF<sub>4</sub>·oxygen-base adducts, the equatorial S–F bonds (1.537(2)–1.547(2) Å) of each SF<sub>4</sub> are significantly shorter than the axial S–F bonds (1.632(3)–1.677(2) Å). These S–F bond lengths are also indistinguishable from those of SF<sub>4</sub> in the solid state (S–F<sub>eq</sub> 1.527(4) and 1.535(4); S–F<sub>ax</sub> 1.647(5) and 1.676(5) Å).<sup>[8]</sup> The F<sub>eq</sub>–S–F<sub>eq</sub> angles of the (SF<sub>4</sub>·O=C(CH<sub>3</sub>)<sub>2</sub>)<sub>2</sub> adduct (99.31(11) and 99.41(13)°) are similar to those of SF<sub>4</sub> in the solid state (101.0(2) and 99.6(3)°) further attesting to the weakness of the Lewis acid-base interactions in the present adduct.<sup>[8]</sup>

The O(1)–S(1)–O(2) and O(1)–S(2)–O(2) angles of [SF<sub>4</sub>·O=C(CH<sub>3</sub>)<sub>2</sub>]<sub>2</sub> are 94.67(7)° and 92.96(7)°, respectively, which are significantly smaller than those in the (SF<sub>4</sub>·THF)<sub>2</sub> dimer (102.12(6)° and 102.03(5)°). As a result, the S(1)–O(1)–S(2) and S(1)–O(2)–S(2) angles are larger (81.69(6)° and 81.95(6)°), as was also observed in the (SF<sub>4</sub>·THF)<sub>2</sub> dimer (77.49 (5)° and 77.97(4)°).

The C=O bonds in [SF<sub>4</sub>·O=C(CH<sub>3</sub>)<sub>2</sub>]<sub>2</sub> (O(1)–C(2) 1.231(4) and O(2)–C(5) 1.219(4) Å) become slightly elongated compared to free acetone (1.208(3) and 1.209(3) Å) upon adduct formation.<sup>[9]</sup> This is a result of SF<sub>4</sub> withdrawing electron density from the carbonyl group consequently elongating the bond. However, this effect is not strong enough to significantly affect the C–C bonds of adducted acetone (1.484(4)–1.496(4) Å) compared to free acetone (1.485(4) and 1.486(4) Å).

DFT calculations were carried out on  $[\text{SF}_4 \cdot \text{O}=\text{C}(\text{CH}_3)_2]_2$  and the gas-phase geometry was optimized using the crystal structure as the starting coordinates. The geometric parameters are shown in Table 3.2. Overall, the calculated bond lengths and bond angles are overestimated compared to the experimental data, largely as a result of the crystal packing in the  $[\text{SF}_4 \cdot \text{O}=\text{C}(\text{CH}_3)_2]_2$  unit cell. The calculated S---O contacts range from 2.923–3.041 Å. The calculated S–F equatorial bond lengths are shorter than the S–F axial bond lengths of  $\text{SF}_4$  observed in the crystal structure. The optimized gas-phase geometry was also calculated for  $\text{SF}_4 \cdot [\text{O}=\text{C}(\text{CH}_3)_2]_2$ , as shown in Figure 3.2, and the bond lengths and bond angles are listed in Table 3.3.

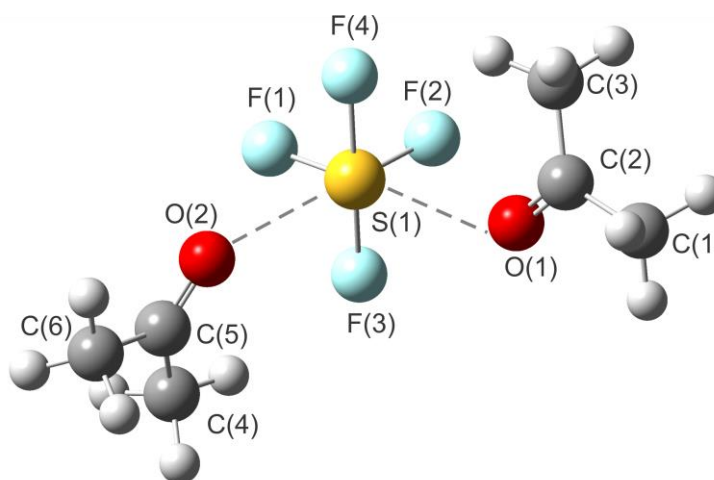

Figure 3.2 Geometry-optimized gas-phase structure of  $\text{SF}_4 \cdot [\text{O}=\text{C}(\text{CH}_3)_2]_2$  at the B3LYP/aug-cc-pVTZ level of theory.

The  $\text{SF}_4 \cdot [\text{O}=\text{C}(\text{CH}_3)_2]_2$  adopts a pseudo octahedral geometry about the S(1) center with the acetone molecules staggered in a *syn* conformation. The constraint observed in the O(1)–S(1)–O(2) angle of the  $(\text{SF}_4 \cdot \text{O}=\text{C}(\text{CH}_3)_2)_2$  dimer ( $93.28^\circ$ ) is not present in  $\text{SF}_4 \cdot [\text{O}=\text{C}(\text{CH}_3)_2]_2$  ( $104.34^\circ$ ) and so, consequently, this calculated angle is larger in the 1:2 adduct. With one less  $\text{SF}_4$ , the calculated S---O contacts (2.899 Å), while still very weak,

are shorter than the ones of  $[\text{SF}_4 \cdot \text{O}=\text{C}(\text{CH}_3)_2]_2$ . The calculated S–F distances and F–S–F angles of both the 1:1 and 1:2 adducts are essentially the same which reflects the weak Lewis basicity of acetone.

Table 3.3 Calculated Bond Lengths (Å) and Angles (°) of  $\text{SF}_4 \cdot [\text{O}=\text{C}(\text{CH}_3)_2]_2$ .

### 3.2.3 Raman Spectroscopy of $[\text{SF}_4 \cdot \text{O}=\text{C}(\text{CH}_3)_2]_2$ and $\text{SF}_4 \cdot [\text{O}=\text{C}(\text{CH}_3)_2]_2$

The low-temperature Raman spectra of the  $[\text{SF}_4 \cdot \text{O}=\text{C}(\text{CH}_3)_2]_2$  and  $\text{SF}_4 \cdot [\text{O}=\text{C}(\text{CH}_3)_2]_2$  adducts were recorded at  $-110^\circ\text{C}$  and are depicted in Figure 3.3. Vibrational frequencies of the geometry-optimized compounds were calculated at the B3LYP/aug-cc-pVTZ level of theory and used to aid in the assignments of the Raman bands. The full analysis and assignments of the Raman spectra can be found in the Appendix Table A.1.1. A summary of selected vibrational frequencies is provided in Table 3.4.

Addition of SF<sub>4</sub> to either one or two equivalents of acetone resulted in the formation of the [SF<sub>4</sub>·O=C(CH<sub>3</sub>)<sub>2</sub>]<sub>2</sub> or SF<sub>4</sub>·[O=C(CH<sub>3</sub>)<sub>2</sub>]<sub>2</sub> adduct, respectively, and the subsequent shift in key vibrational frequencies of acetone and SF<sub>4</sub>. The C=O stretching frequency of [SF<sub>4</sub>·O=C(CH<sub>3</sub>)<sub>2</sub>]<sub>2</sub> (1699 and 1694 cm<sup>-1</sup>) and SF<sub>4</sub>·[O=C(CH<sub>3</sub>)<sub>2</sub>]<sub>2</sub> (1702 cm<sup>-1</sup>) was shifted to a lower frequency compared to free acetone (1709 cm<sup>-1</sup>). Upon adduct formation, SF<sub>4</sub> withdraws electron density from the C=O bond consequently weakening it which results in a shift to lower frequency. This also results in the strengthening of the C–C bonds which was observed in the Raman spectrum by an increase in the ν<sub>as</sub> and ν<sub>s</sub> (CCC) frequencies of [SF<sub>4</sub>·O=C(CH<sub>3</sub>)<sub>2</sub>]<sub>2</sub> (1236; 798 and 794 cm<sup>-1</sup>) and SF<sub>4</sub>·[O=C(CH<sub>3</sub>)<sub>2</sub>]<sub>2</sub> (1230; 794 cm<sup>-1</sup>) relative to acetone (1222; 788 cm<sup>-1</sup>). The Raman bands of acetone are not greatly shifted, which is in accordance with the observations for other SF<sub>4</sub>·oxygen-base adducts. The SF<sub>4</sub>·(O=C<sub>5</sub>H<sub>8</sub>)<sub>2</sub> adduct showed a decrease in the C=O stretching frequency from 1743/1728 cm<sup>-1</sup>, for cyclopentanone, to 1724/1712 cm<sup>-1</sup>.<sup>[5]</sup> The C–C stretches for other SF<sub>4</sub>·oxygen-base adducts are also shifted by small amounts and show vibrational coupling.<sup>[5]</sup>

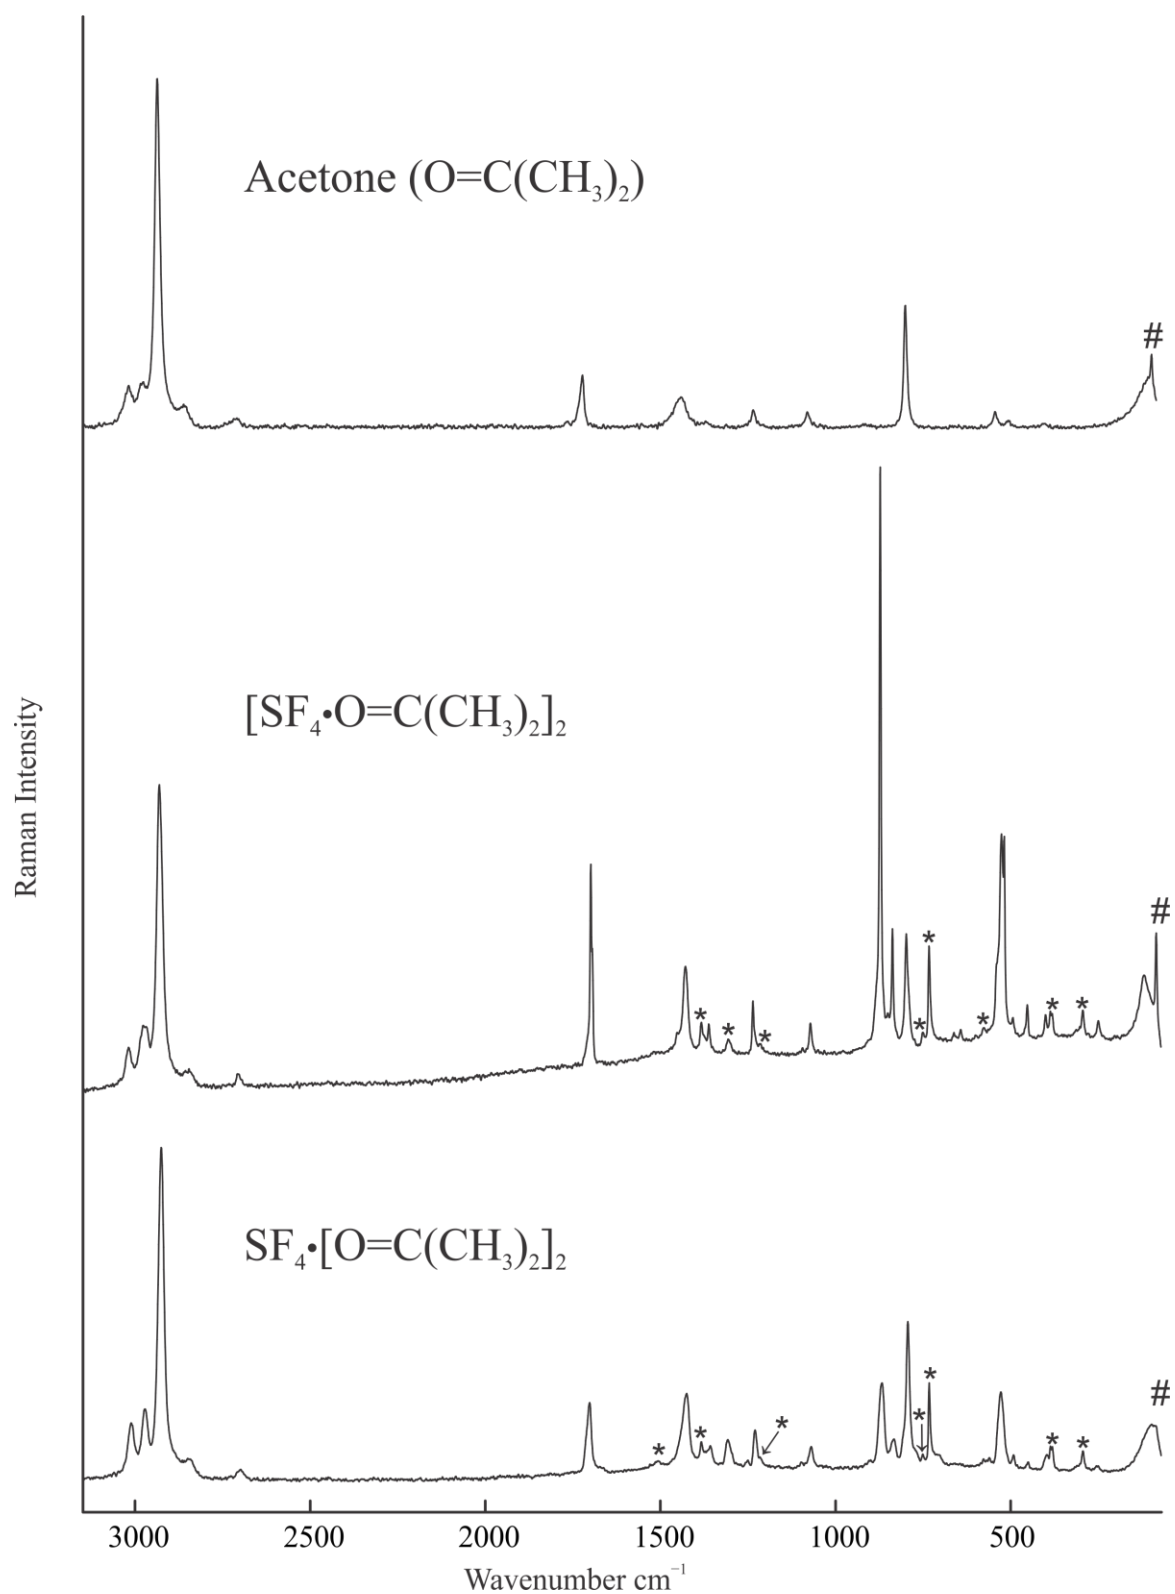

Figure 3.3 Raman spectrum of  $\text{O}=\text{C}(\text{CH}_3)_2$ ,  $\text{SF}_4 \cdot [\text{O}=\text{C}(\text{CH}_3)_2]_2$  and  $[\text{SF}_4 \cdot \text{O}=\text{C}(\text{CH}_3)_2]_2$  at  $-110\text{ }^\circ\text{C}$ . Symbols denote bands arising from FEP sample tube (\*), and an instrumental artifact (#).

<sup>a</sup> The abbreviations denote symmetric (s), asymmetric (as), equatorial (eq), axial (ax), stretch ( $\nu$ ), shoulder (sh), and not observed (n.o.). <sup>b</sup> The experimental gas-phase vibrational frequencies and assignments from Ref. 10. <sup>c</sup> The calculated vibrational frequencies and assignments from Ref 10. <sup>d</sup> Raman intensities, in  $\text{\AA}^4 \text{u}^{-1}$ , are given in parentheses. <sup>e</sup> DFT calculations at the B3LYP/aug-cc-pVTZ level of theory.

The S–F stretching bands of the adducts are all shifted to lower frequencies upon adduct formation reflecting an increase in ionic character of the S–F bonds in SF<sub>4</sub>. The most intense band in the  $[\text{SF}_4 \cdot \text{O}=\text{C}(\text{CH}_3)_2]_2$  Raman spectrum, at 873  $\text{cm}^{-1}$ , is associated with the  $\nu_{\text{s}}(\text{SF}_{2, \text{eq}})$  mode and is significantly shifted to a lower frequency compared to free SF<sub>4</sub> (892  $\text{cm}^{-1}$ ). As well, the  $\nu_{\text{s}}(\text{SF}_{2, \text{ax}})$  mode is dramatically lowered to 526/519  $\text{cm}^{-1}$  compared to free SF<sub>4</sub> (558  $\text{cm}^{-1}$ ). Many of the S–F bands in the  $[\text{SF}_4 \cdot \text{O}=\text{C}(\text{CH}_3)_2]_2$  Raman spectrum show splitting into two bands which can be associated with vibrational coupling of the two SF<sub>4</sub> moieties in the  $[\text{SF}_4 \cdot \text{O}=\text{C}(\text{CH}_3)_2]_2$  dimer. These splittings were also

predicted in the calculated vibrational frequencies for the gas-phase optimized geometry. Similar shifts to lower frequencies in the  $\nu_s(\text{SF}_{2,\text{eq}})$  and  $\nu_s(\text{SF}_{2,\text{ax}})$  modes were also detected in  $\text{SF}_4 \cdot [\text{O}=\text{C}(\text{CH}_3)_2]_2$  Raman spectrum (868; 528  $\text{cm}^{-1}$ ).

### 3.2.4 X-ray Crystallography of $\text{SF}_4 \cdot (\text{O}=\text{C}_{10}\text{H}_{14}) \cdot (\text{HF})$

The crystallographic parameters and details of data collection for  $\text{SF}_4 \cdot (\text{O}=\text{C}_{10}\text{H}_{14}) \cdot (\text{HF})$  are given in Table 3.5. The bond lengths and bond angles are listed in Table 3.6. The data showed a completeness of 88% to  $136.388^\circ$  as a result of the twinned nature of the crystal.

The  $\text{SF}_4 \cdot (\text{O}=\text{C}_{10}\text{H}_{14}) \cdot (\text{HF})$  crystallized in the  $P3_2$  space group and contains chains of alternating  $\text{SF}_4$ ,  $\text{O}=\text{C}_{10}\text{H}_{14}$ , and HF molecules (Figure 3.4). Each  $\text{SF}_4$  has one S---O chalcogen bond to an oxygen atom, (S(1)---O(2) 2.969(4); S(2)---O(3) 2.973(4); S(3)---O(1) 3.060(4) Å) from 2-adamantanone, and a second S---F chalcogen bond to a fluorine atom of HF (S(1)---F(1) 2.784(4); S(2)---F(6) 2.835(3); S(3)---F(11) 2.728(4) Å), which in turn is hydrogen-bonded to an oxygen atom of 2-adamantanone (O(1)---F(1) 2.462(5); O(2)---F(6) 2.489(5); O(3)---F(11) 2.469(4) Å). Previous crystal structures of  $(\text{SF}_4 \cdot \text{O}=\text{C}(\text{CH}_3)_2)_2$  and  $\text{SF}_4 \cdot (\text{O}=\text{C}_5\text{H}_8)_2$  have contained S---O chalcogen bonds between  $\text{SF}_4$  and a ketone ranging from 2.842(2)–2.899(2) Å and 2.7952(12)–2.7880(12) Å, respectively.<sup>[5]</sup> The S---O chalcogen bonding interactions in  $\text{SF}_4 \cdot (\text{O}=\text{C}_{10}\text{H}_{14}) \cdot (\text{HF})$  are even weaker but still smaller than the sum of the van der Waals radii (3.32 Å).<sup>[11]</sup> This O---(HF)---S secondary bonding interaction is the first example where HF is bridging a sulfur atom of  $\text{SF}_4$  to an oxygen atom of a ketone. The crystal structure of  $\text{C}_8\text{H}_{10}\text{N}_4\text{O}_2 \cdot 2\text{SF}_4 \cdot \text{HF}$  showed HF hydrogen-bonded to a Lewis basic nitrogen atom of caffeine with an N---(HF)---S

linkage. In this structure caffeine forms an adduct with SF<sub>4</sub> through similarly weak C=O--S chalcogen bonding interactions (up to 2.9954(18) Å).<sup>[5]</sup>

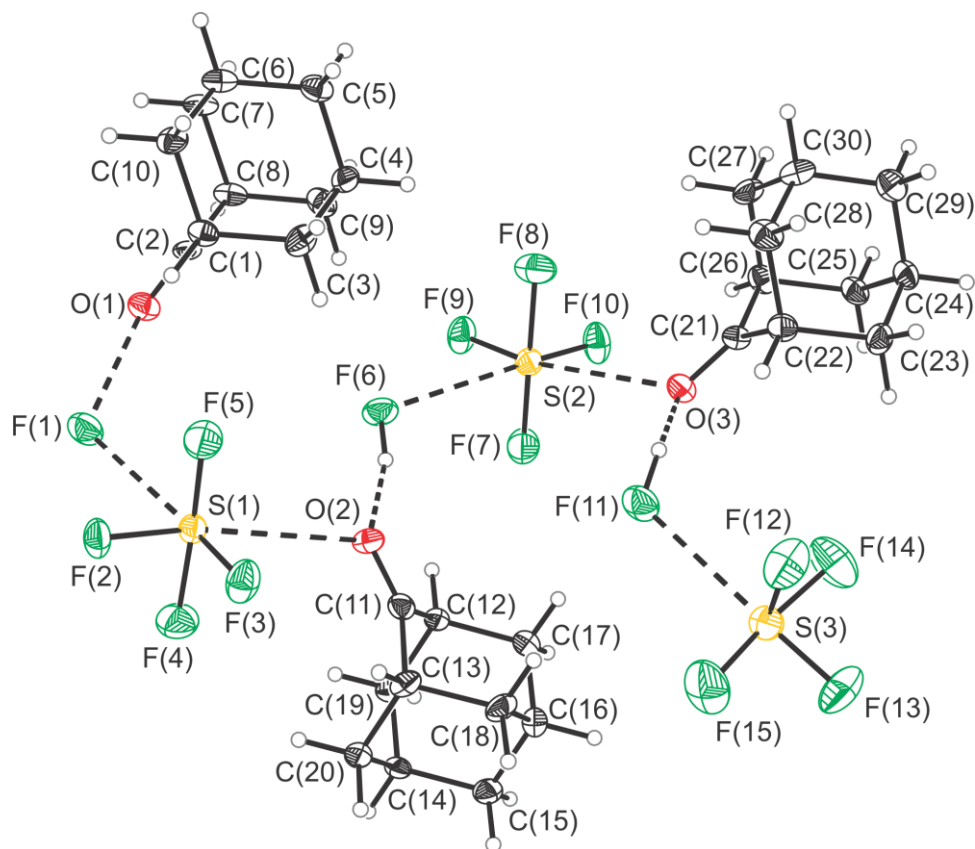

Figure 3.4 Thermal ellipsoid plots of  $\text{SF}_4 \cdot (\text{O}=\text{C}_{10}\text{H}_{14}) \cdot (\text{HF})$ . Thermal ellipsoids are set at the 50% probability level.

The C=O bond of each 2-adamantanone are slightly elongated in  $\text{SF}_4 \cdot (\text{O}=\text{C}_{10}\text{H}_{14}) \cdot (\text{HF})$  ( $\text{O}(1)=\text{C}(1)$  1.241(6);  $\text{O}(2)=\text{C}(11)$  1.229(6);  $\text{O}(3)=\text{C}(21)$  1.232(6) Å) compared to non-adducted 2-adamantanone (1.215(3) Å).<sup>[12]</sup> This is a result of weakly Lewis acidic  $\text{SF}_4$  withdrawing electron density from the carbonyl bond upon adduct formation, typical of  $\text{SF}_4$ ·oxygen-base adducts. Previous adducts of  $\text{SF}_4$  with pyridine, and its derivatives, by solvolysis with HF, included the protonation of the nitrogen base which, in turn, resulted in the formation of  $\text{F}_4\text{S} \cdots (\text{F}) \cdots \text{HN}$  interactions.<sup>[13]</sup> This is not the case for the crystal structure of  $\text{SF}_4 \cdot (\text{O}=\text{C}_{10}\text{H}_{14}) \cdot (\text{HF})$  as two of the three protons were found in the electron difference map bonded to a fluorine atom forming HF as opposed to protonation

of the oxygen of the carbonyl group. In contrast to pyridine, the carbonyl group is not basic enough to be protonated under these conditions.<sup>[6]</sup> If the C=O group was protonated by HF, the C=O bond length would be even more elongated, as was previously observed for the oxonium cation  $[\text{HO}=\text{C}_{10}\text{H}_{14}]^+$  (1.274(2) Å) in the solid state.<sup>[14]</sup> Deoxofluorination reactions of ketones with  $\text{SF}_4$  typically require at least a catalytic amount of HF in order to generate, what is believed to be the active species,  $[\text{SF}_3]^+$  and  $[\text{HF}_2]^-$ . The reaction mixture of  $\text{SF}_4$ , HF, and 2-adamantanone should result in the deoxofluorination of the carbonyl group to a  $-\text{CF}_2$  group under more severe reaction conditions. The crystal structure of  $\text{SF}_4 \cdot (\text{O}=\text{C}_{10}\text{H}_{14}) \cdot (\text{HF})$  illustrates the interactions between these three molecules prior to the possible deoxofluorination of 2-adamantanone. It shows the weakening of the C=O bond as a result of the F–H---O=C interaction. The presence of a F–H---FSF<sub>3</sub> linkage is not present, despite the assumption that the first step of a deoxofluorination reaction is the generation of  $[\text{SF}_3]^+$  and  $[\text{HF}_2]^-$ .

### 3.3 Summary and Conclusions

The Lewis acid-base adduct between  $\text{SF}_4$  and acetone, the simplest aliphatic ketone, has long been sought-after and has now finally been synthesized and characterized in the solid state. The  $\text{SF}_4 \cdot [\text{O}=\text{C}(\text{CH}_3)_2]_2$  and  $[\text{SF}_4 \cdot (\text{O}=\text{C}(\text{CH}_3)_2)]_2$  adducts were both characterized by Raman spectroscopy which showed shifts in characteristic bands associated with the acetone molecules. The C=O stretch decreased by 7 and 10  $\text{cm}^{-1}$  for  $\text{SF}_4 \cdot [\text{O}=\text{C}(\text{CH}_3)_2]_2$  and  $[\text{SF}_4 \cdot (\text{O}=\text{C}(\text{CH}_3)_2)]_2$ , respectively. These small changes in frequency are a result of the weak interactions between  $\text{SF}_4$  and acetone. The symmetric and asymmetric stretches of the  $\text{SF}_2$  moieties in  $\text{SF}_4$  showed significant decreases as well. The most notable is the symmetric

(SF<sub>2</sub>)-equatorial stretch which decreased by 24 cm<sup>-1</sup> for SF<sub>4</sub>·[O=C(CH<sub>3</sub>)<sub>2</sub>]<sub>2</sub> and 19 cm<sup>-1</sup> for [SF<sub>4</sub>·(O=C(CH<sub>3</sub>)<sub>2</sub>)<sub>2</sub>]<sub>2</sub>. A single crystal of the thermally unstable (SF<sub>4</sub>·(O=C(CH<sub>3</sub>)<sub>2</sub>)<sub>2</sub>) was successfully isolated and the X-ray crystal structure confirmed the weak interactions between acetone and SF<sub>4</sub> with S---O distances ranging from 2.842(2)–2.899(2) Å. DFT calculations of the gas-phase optimized geometry of the [SF<sub>4</sub>·(O=C(CH<sub>3</sub>)<sub>2</sub>)<sub>2</sub>] dimer typically overestimate the bond lengths and bond angles which was attributed [SF<sub>4</sub>·(O=C(CH<sub>3</sub>)<sub>2</sub>)<sub>2</sub>] being in the gas phase as opposed to the solid state where crystal packing likely resulted in more constrained geometric parameters.

The crystal structure of SF<sub>4</sub>·(O=C<sub>10</sub>H<sub>14</sub>)·(HF) shows a new bonding modality where HF bridges a ketone and SF<sub>4</sub> via O---(HF)---S secondary bonding interactions creating a chained packing arrangement. Also present were weak S---O chalcogen bonding interactions with distances of 2.969(3)–3.060(4) Å. This F–H---O=C interaction is in contrast to a F–H---FSF<sub>3</sub> interaction which would lead to the proposed intermediate [SF<sub>3</sub>]<sup>+</sup> in deoxofluorination reactions. This X-ray crystal structure could shed light onto the reaction mechanism of deoxofluorination reactions involving SF<sub>4</sub>. However, in solution the interactions between all species are dynamic and this structure may not represent the relevant interactions for the actual reaction pathway.

## 4. Lewis Acid-Base Adducts of $[\text{SF}_3]^+$ with Ketones

### 4.1 Introduction

Deoxofluorination reactions are commonly used in organic chemistry as a means of transforming either an alcohol, ketone, or carboxylic acid to a  $-\text{CF}$ ,  $-\text{CF}_2$ , or  $-\text{CF}_3$  group, respectively.<sup>[1–4]</sup> The archetypical deoxofluorinating reagent is sulfur tetrafluoride,  $\text{SF}_4$ .<sup>[2]</sup> The reaction mechanism for deoxofluorination reactions with  $\text{SF}_4$  is speculated to include a reactive species responsible for polarizing the  $\text{C}=\text{O}$  bond, consequently allowing for a nucleophilic fluoride source to attack the carbon center and generate the desired  $\text{C}-\text{F}$  bond. Mechanisms for deoxofluorination have been proposed (see Chapter 1, Section 1.1.1). One proposed intermediate for this mechanism is the  $[\text{SF}_3]^+$  cation adducted to a carbonyl group. Another is the neutral alkoxysulfur trifluoride,  $\text{ROSF}_3$ , however, there are only a few reports of such a species existing.<sup>[5,6]</sup>

### 4.2 Results and Discussion

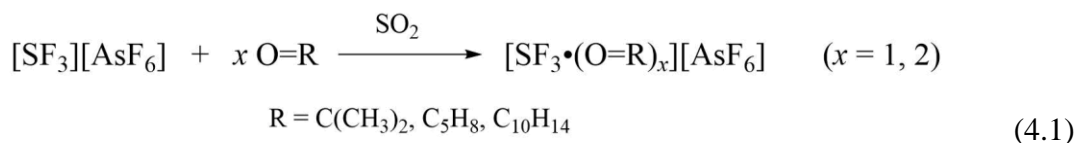

#### 4.2.1 Synthesis of $[\text{SF}_3][\text{AsF}_6]$ with the Ketones Acetone, Cyclopentanone, and 2-Adamantanone

In an effort to synthesize adducts of  $[\text{SF}_3]^+$  with ketones, the  $[\text{SF}_3][\text{AsF}_6]$  salt was reacted with approximately one or two molar equivalents of cyclopentanone and 2-adamantanone. In the case of acetone, 1–3 equivalents were used, as well as, an excess of acetone (i.e., as the solvent). Sulfur dioxide (m.p. =  $-72\text{ }^\circ\text{C}$ ) was chosen as the solvent for the stoichiometric reactions as both the ketones and  $[\text{SF}_3][\text{AsF}_6]$  were highly soluble in it resulting in solutions even at low temperatures. As the only exception, the reaction of  $[\text{SF}_3]^+$  with two equivalents of 2-adamantanone resulted in precipitation of a white solid at  $-70$

°C. The  $[\text{SF}_3]^+$  cation does not react with  $\text{SO}_2$  making it an ideal polar solvent. The solubility of  $[\text{SF}_3][\text{AsF}_6]$  was tested in other solvents including  $\text{CH}_2\text{Cl}_2$ ,  $\text{CFC}_3$ , and  $\text{SO}_2\text{ClF}$ , however, it was found to be insoluble. Attempts to carry out these reactions in anhydrous HF resulted in the generation of a superacidic solution where protonation of the ketones was observed as opposed to adduct formation (see Chapter 5 for these results). Solvents containing a nitrogen base (i.e. pyridine and acetonitrile) were avoided since their higher basicity would result in the formation of  $[\text{SF}_3 \cdot (\text{N-base})_2]^+$  adducts, as previously shown.<sup>[7]</sup>

Reactions of  $[\text{SF}_3][\text{AsF}_6]$  with acetone, cyclopentanone, and 2-adamantanone were carried out in  $\text{SO}_2$  starting at  $-70^\circ\text{C}$  (Equation 4.1) and were allowed to gradually warm to higher temperatures (up to RT) for controlled periods of time while using  $^{19}\text{F}$  and  $^1\text{H}$  NMR spectroscopy at  $-70^\circ\text{C}$  to monitor the progress of the reaction. When two equivalents of 2-adamantanone were reacted with  $[\text{SF}_3][\text{AsF}_6]$  in  $\text{SO}_2$  at  $-70^\circ\text{C}$ , an insoluble white solid was present and required the reaction mixture to be warmed to  $-40^\circ\text{C}$  to dissolve the unidentified product. Due to the challenges associated with working on a small scale ( $< 40$  mg of  $[\text{SF}_3][\text{AsF}_6]$ ), volumes of the ketones, acetone and cyclopentanone, were measured to the nearest 0.01 mL or 0.001 g and only approximate ratios were obtained. The  $[\text{SF}_3 \cdot (\text{O-base})_x][\text{AsF}_6]$  ( $x = 1-3$ ) adducts were attempted to be characterized in the solid state using LT Raman spectroscopy, but removal of  $\text{SO}_2$  under dynamic vacuum consistently resulted in either dark brown or purple powders that could not be identified due to large fluorescence in the Raman spectrum. These adducts were also highly sensitive to temperature and moisture in  $\text{SO}_2$  solutions resulting in dark red or orange solutions when warmed to RT. In some instances, when the reaction was not carefully controlled and kept at  $-70^\circ\text{C}$ , small dark orange spots would appear on the top of the 1/4-in. o.d. FEP reactors.

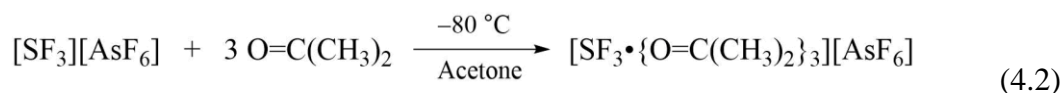

These unidentified decomposition products were a result of parts of the reactor being at RT. When these came in contact with the bulk sample, an immediate colour change of the sample from colourless to dark orange appeared indicating the decomposition of the  $[\text{SF}_3 \cdot (\text{O-base})_x]^+$  adduct.

#### 4.2.2 $[\text{SF}_3][\text{AsF}_6]$ in Excess Acetone

The reaction of  $[\text{SF}_3][\text{AsF}_6]$  with excess acetone, i.e., acetone as the solvent, was carried out at  $-80^\circ\text{C}$  (m.p. of acetone =  $-94.7^\circ\text{C}$ ), and allowed to warm up for carefully controlled periods of time. The  $^{19}\text{F}$  NMR spectra are depicted in Figure 4.1 and the chemical shifts and coupling constants listed in Table 4.1. Upon melting the mixture of acetone and  $[\text{SF}_3][\text{AsF}_6]$  at  $-80^\circ\text{C}$ , a clear and colourless solution formed. The  $^{19}\text{F}$  NMR spectrum (Figure 4.1) contained resonances at 18.43 ppm, tentatively assigned to the  $[\text{SF}_3 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_3]^+$  adduct cation, and  $-63.94$  ppm, associated with the  $[\text{AsF}_6]^-$  anion (Equation 4.2). The chemical shift of  $[\text{SF}_3]^+$  in  $\text{SO}_2$  appears at 32.91 ppm as a singlet and the  $[\text{AsF}_6]^-$  resonance of  $[\text{SF}_3][\text{AsF}_6]$  in  $\text{SO}_2$  solvent is a broad singlet at  $-58.53$  ppm. Upon dissolving this salt in acetone, a Lewis basic solvent, the chemical shift of  $[\text{SF}_3]^+$  decreases in frequency to 18.43 ppm due to the donation of electron density from the oxygen of acetone to sulfur. This leads to the S–F bonds being slightly more ionic which results in a significant decrease in the chemical shift. Evidence for the coordination of three acetone molecules to  $[\text{SF}_3]^+$  is also detected by the shape of the  $^{19}\text{F}$  resonance for  $[\text{AsF}_6]^-$  which appears as a sharp equal-intensity quartet. The sulfur center of  $[\text{SF}_3]^+$  has three additional

contacts with the anions in solid  $[\text{SF}_3][\text{AsF}_6]$  and  $[\text{SF}_3][\text{SbF}_6]$  resulting in a coordination number of 6.<sup>[7]</sup> Only with strong bases, such as pyridine, has sulfur of  $[\text{SF}_3]^+$  been observed to accept only 2 dative bonds forming the  $[\text{SF}_3(\text{NC}_5\text{H}_5)_2]^+$  cation.<sup>[7]</sup> The observation of a sharp quartet with a  $^1J(^{75}\text{As}-^{19}\text{F}) = 934 \text{ Hz}$  is a consequence of a negligible electric field gradient about  $^{75}\text{As}$  ( $I = 3/2$ , 100%), causing slow quadrupolar relaxation. This indicates the anion is perfectly isolated adopting an octahedral geometry with no contacts to the cation.

While no changes were observed when the reaction was warmed to  $-60^\circ\text{C}$ , at  $-40^\circ\text{C}$  the solution turned an orange/brown colour. The  $^{19}\text{F}$  resonance for the  $[\text{SF}_3 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_3]^+$  cation (18.42 ppm) was no longer present and, instead, two new resonances at 76.88 ( $F_{\text{ax}}$  of  $\text{SF}_4$ ) and 30.16 ppm ( $F_{\text{eq}}$  of  $\text{SF}_4$ ) appeared due to the formation of  $\text{SF}_4$ , with scalar  $^2J(^{19}\text{F}-^{19}\text{F})$  coupling of 68.6 Hz between the equatorial and axial fluorine atoms. The  $[\text{SF}_3 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_3][\text{AsF}_6]$  compound seems to undergo a dismutation reaction presumably forming the elusive and highly reactive  $[\text{SF}_2 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_3][\text{AsF}_6]_2$  compound in addition to  $\text{SF}_4$  (Equation 4.3). The proposed dismutation reaction is supported by the observed integration of 1.9:2.0:10.3 for the axial and equatorial fluorine environments of  $\text{SF}_4$  and  $[\text{AsF}_6]^-$  after warming the reaction mixture to  $-40^\circ\text{C}$ . However, the  $[\text{SF}_2 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_3]^{2+}$  cation is expected to be highly reactive, i.e., strongly oxidizing, and likely reacts with acetone to form a radical cation which would account for the intense dark purple colour of the solution.

Table 4.1 Selected  $^{19}\text{F}$  chemical shifts ( $\delta$ ) at  $-80\text{ }^{\circ}\text{C}$  for the reaction of  $[\text{SF}_3][\text{AsF}_6]$  with excess acetone.

HF	-180.84 (s, br)	--	--

<sup>a</sup> Abbreviations: (s) singlet; (t) triplet; (q) quartet; (ax) axial; (eq) equatorial; (br) broad.  
<sup>b</sup>  $\Delta\delta(^{34}\text{S}-^{32}\text{S}) = 0.065\text{ ppm}$ . <sup>c</sup>  $^1\Delta(^{34}/^{32}\text{S}) = 0.057\text{ ppm}$ .

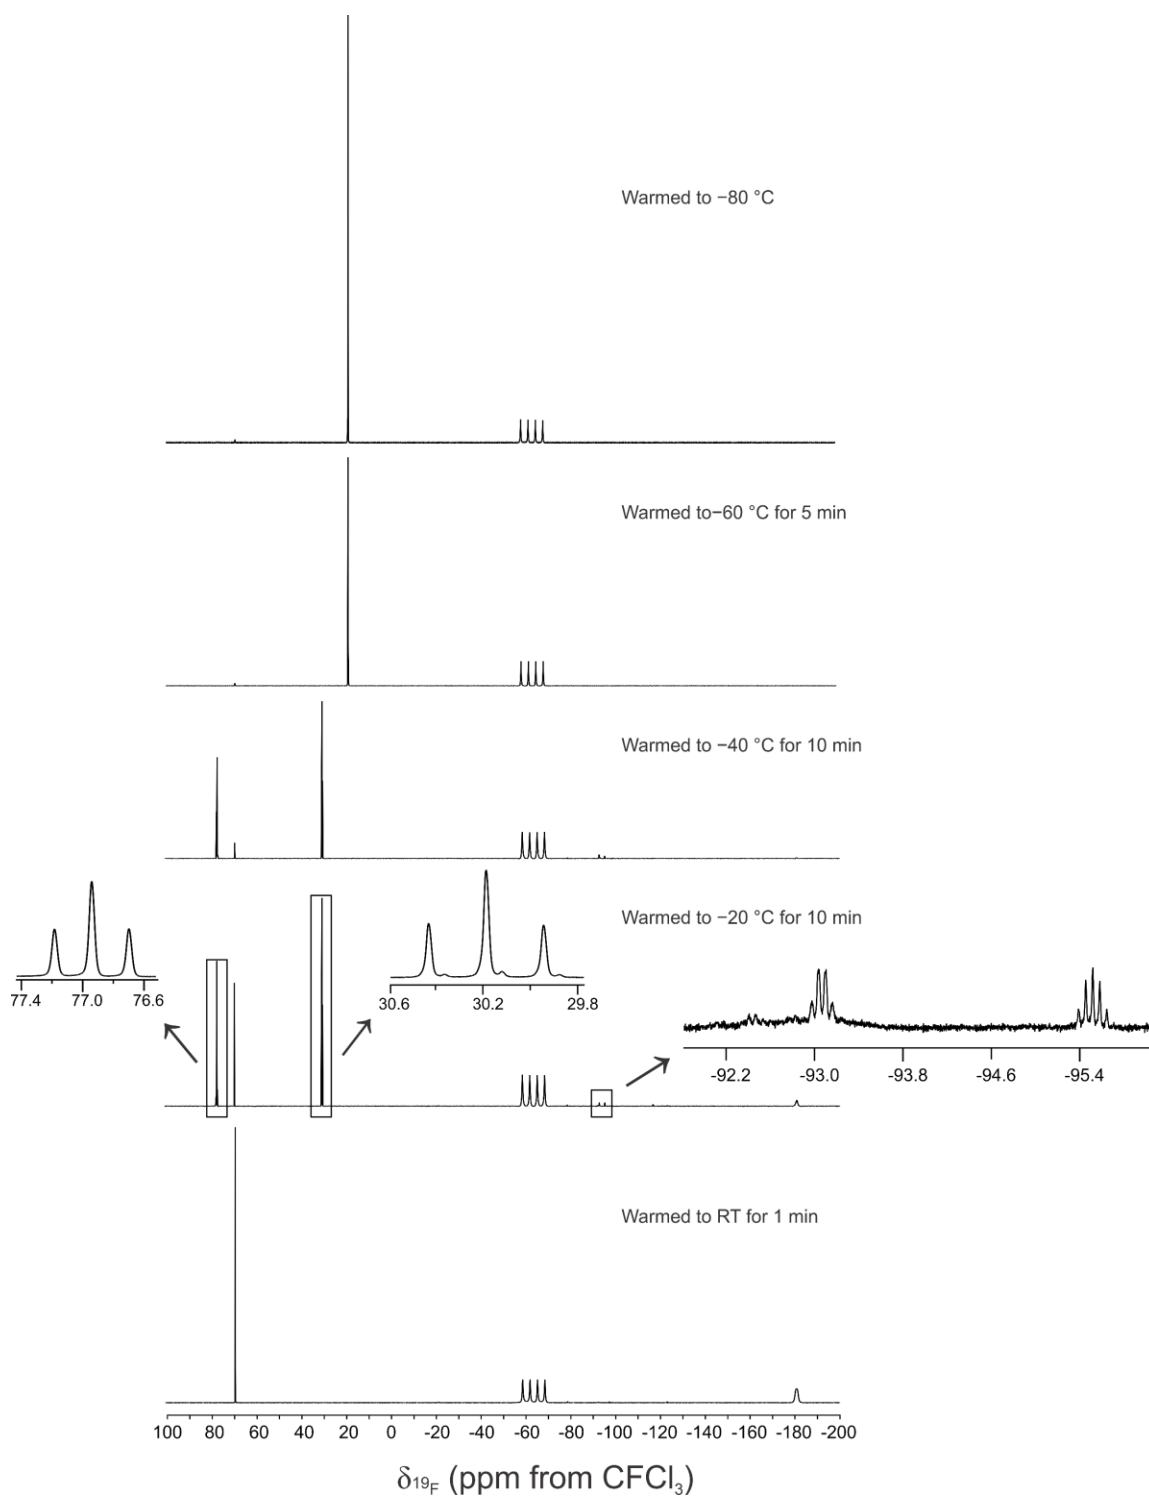

Figure 4.1  $^{19}\text{F}$  NMR spectrum (282.40 MHz) of  $[\text{SF}_3][\text{AsF}_6]$  dissolved in excess acetone at -80 °C. Reaction warmed from -80 °C to RT. Externally referenced to  $\text{CFCl}_3$  at RT.

After warming to  $-20\text{ }^{\circ}\text{C}$  for 10 min,  $\text{SOF}_2$  and HF were observed, by-products of deoxofluorination, as well as some weak resonances at  $-93.1$  (quartet;  $J = 17.6\text{ Hz}$ ) and  $-95.5\text{ ppm}$  (septet;  $J = 18.2\text{ Hz}$ ). The assignments of a septet multiplicity is based on the relative intensities of the observed central five transitions (expected: 1:6:15:20:15:6:1 for septet; 1:4:6:4:1 for quintet) which provides an excellent fit to the experimentally observed relative intensities. These two multiplets contain coupling constants in the range characteristic of  $^3J(^{19}\text{F}-^1\text{H})$  (fluorocarbenium cation  $[(\text{CH}_3)_2\text{CF}]^+$ :  $^3J(^{19}\text{F}-^1\text{H}) = 26\text{ Hz}$ ;  $\delta(^{19}\text{F}) = 182\text{ ppm}$ ;  $\delta(^1\text{H}) = 3.9\text{ ppm}$ ; difluoropropane  $\text{CF}_2(\text{CH}_3)_2$ :  $^3J(^{19}\text{F}-^1\text{H}) = 19\text{ Hz}$ ;  $\delta(^{19}\text{F}) = -81.5\text{ ppm}$ ;  $\delta(^1\text{H}) = 1.37\text{ ppm}$ ).<sup>[8]</sup> The resonances assigned to  $\text{SF}_4$  ( $76.94$  and  $30.19\text{ ppm}$ ) appear as sharp triplets, however, they are shifted to lower frequencies compared to when  $\text{SF}_4$  is dissolved in  $\text{SO}_2$  ( $85.9$  and  $34.1\text{ ppm}$ ) (Table 4.2) where two broad singlets are observed (Figure 4.2). Acetone forms chalcogen bonding interactions with  $\text{SF}_4$  donating electron density from the oxygen of the carbonyl group to the sulfur along the equatorial plane (see Chapter 3 for results pertaining to the solid-state interactions of  $\text{SF}_4$  and acetone). This results in larger shifts of the resonances of the F-axial ligands of  $\text{SF}_4$  ( $\Delta\delta = 9.0\text{ ppm}$ ), making the bonds slightly more ionic, compared to the change in chemical shift of the F-equatorial ligands ( $\Delta\delta = 3.9\text{ ppm}$ ). This was confirmed by mixing  $\text{SF}_4$  with excess acetone (i.e., the solvent) which showed two sharp triplet  $^{19}\text{F}$  resonances at  $77.80$  and  $30.53\text{ ppm}$  (Figure 4.3) even after warming to RT for 1 h. The two triplets were observed in the presence of HF, which usually facilitates rapid exchange between the axial and equatorial fluorine environments, even at low temperatures. This is an indication that  $\text{SF}_4$ , in the presence of excess acetone, is not the reactive species responsible for deoxofluorination or any decomposition products.

Table 4.2  $^{19}\text{F}$  chemical shifts ( $\delta$ ) of  $\text{SF}_4$  in  $\text{SO}_2$  and acetone, as well as a mixture of  $\text{SF}_4$  with  $[\text{SF}_3][\text{AsF}_6]$  in  $\text{SO}_2$  at  $-70\text{ }^\circ\text{C}$ .

Compounds	Solvent	$\delta$ of $\text{SF}_4$ or $[\text{SF}_3]^+$ (ppm) <sup>a</sup>	$^2J(^{19}\text{F}-^{19}\text{F})$ (Hz)	$\delta$ of $[\text{AsF}_6]^-$ (ppm)

<sup>a</sup> Abbreviations: (s) singlet; (t) triplet; (ax) axial; (eq) equatorial; (br) broad.

<sup>b</sup>  $^1\Delta^{19}\text{F}(^{34/32}\text{S}) = 0.066\text{ ppm}$ . <sup>c</sup> Mixed in a 1:1 ratio. <sup>d</sup>  $^1\Delta^{19}\text{F}(^{34/32}\text{S}) = 0.069\text{ ppm}$ .

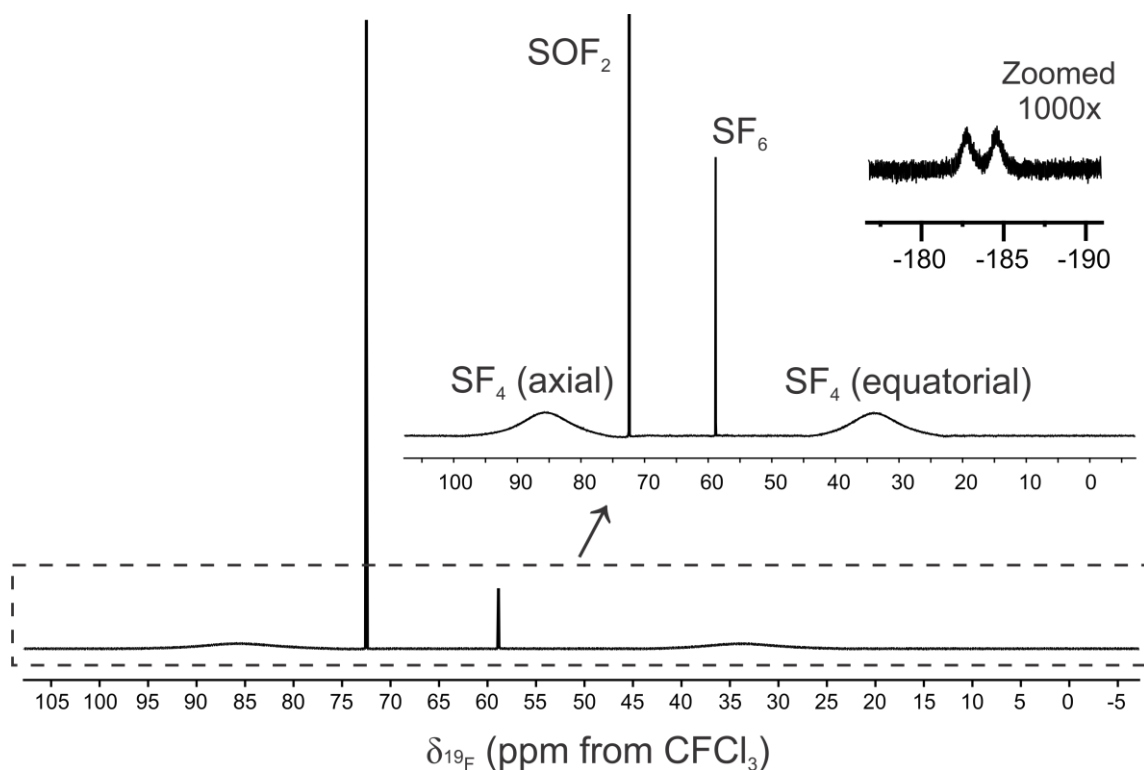

Figure 4.2  $^{19}\text{F}$  NMR spectrum (282.40 MHz) of  $\text{SF}_4$  in  $\text{SO}_2$  at  $-70\text{ }^\circ\text{C}$ . Externally referenced to  $\text{CFCF}_3$  at RT.

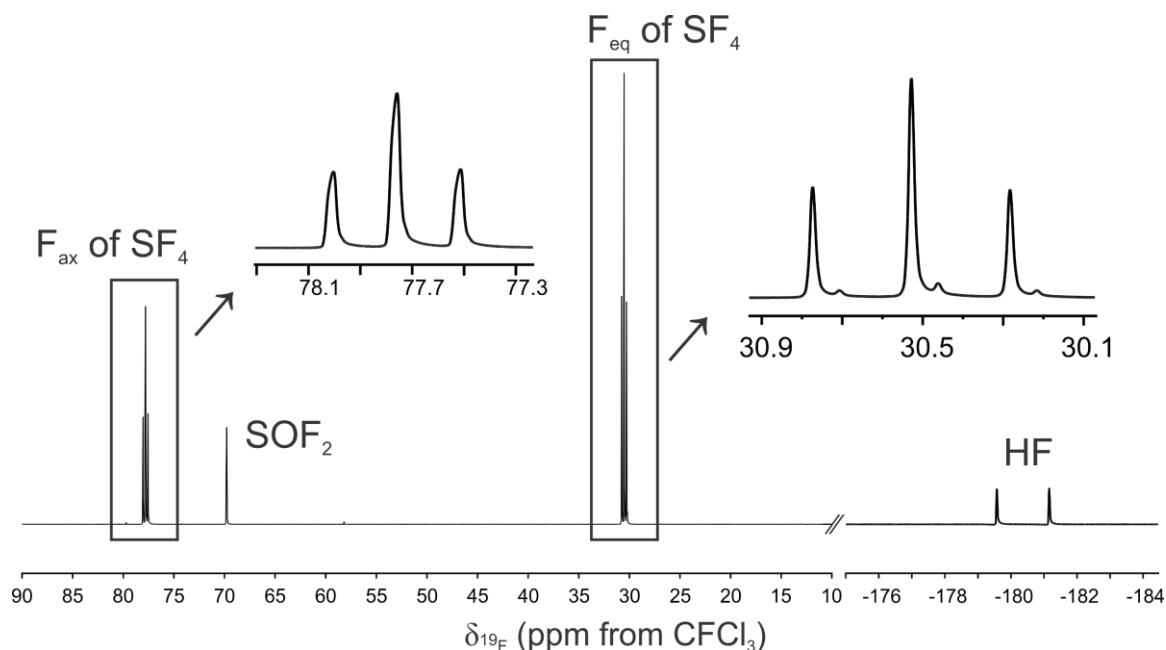

Figure 4.3  $^{19}\text{F}$  NMR spectrum (282.40 MHz) of  $\text{SF}_4$  in excess acetone at  $-70\text{ }^\circ\text{C}$ . Sample was warmed to RT for 1 h. Externally referenced to  $\text{CFCl}_3$  at RT.

After the reaction was brought to RT for 1 min, no  $\text{SF}_4$  remained. The only resonances observed were  $\text{SOF}_2$ , two equivalents of  $[\text{AsF}_6]^-$ , and four equivalents HF with integration ratios of 2.0:12.0:4.4 indicating complete deoxofluorination of acetone, with respect to the  $\text{SF}_4$  generated via the dismutation (Equation 4.3). The nature of the cation in solution could not be identified as it is likely a radical cation which will not be observable by NMR spectroscopy. A potential radical cationic deoxofluorination product decomposed to generate HF as four equivalents of HF accounts for all fluorines, besides those of  $\text{SOF}_2$ ; two from the  $\text{SF}_4$  reacting to yield  $\text{SOF}_2$ , and two from the proposed  $[\text{SF}_2]^{2+}$  species. The origin of the hydrogens in HF are likely the methyl groups of acetone as stoichiometric amounts of HF via hydrolysis from moisture contamination can be excluded. The fate of the sulfur from  $[\text{SF}_2]^{2+}$  is also not understood.

Proton NMR spectroscopy was used to characterize the reaction contents, however, since acetone was used as the solvent, only a singlet resonance was observed at 2.01 ppm. The strong colour change to dark orange/brown is likely a result of either the paramagnetic reaction product or fast chemical exchange between acetone solvent and adducted acetone.

#### **4.2.3 [SF<sub>3</sub>][AsF<sub>6</sub>] and Three Equivalents of Acetone in SO<sub>2</sub>**

The reaction involving three molar equivalents of acetone with [SF<sub>3</sub>][AsF<sub>6</sub>] in SO<sub>2</sub> resulted in clear, colourless solutions upon melting at  $-70\text{ }^{\circ}\text{C}$ . The <sup>19</sup>F NMR spectra are depicted in Figure 4.4 and the chemical shifts and coupling constants are listed in Table 4.3.

Table 4.3 Selected  $^{19}\text{F}$  chemical shifts ( $\delta$ ) at  $-70\text{ }^{\circ}\text{C}$  for the reaction of  $[\text{SF}_3][\text{AsF}_6]$  with three molar equivalents of acetone in  $\text{SO}_2$ .

<sup>a</sup> Abbreviations: (s) singlet; (t) triplet; (sept) septet; (sh) shoulder; (ax) is axial; (eq) equatorial. <sup>b</sup> Unidentified impurity at  $-16$  ppm. <sup>c</sup>  $^1\Delta^{19}\text{F}(^{34}/^{32}\text{S}) = 0.060$  ppm. <sup>d</sup> Quadrupolar broadened. <sup>e</sup>  $^3J(^{19}\text{F}-^1\text{H}) = 18.9$  Hz.

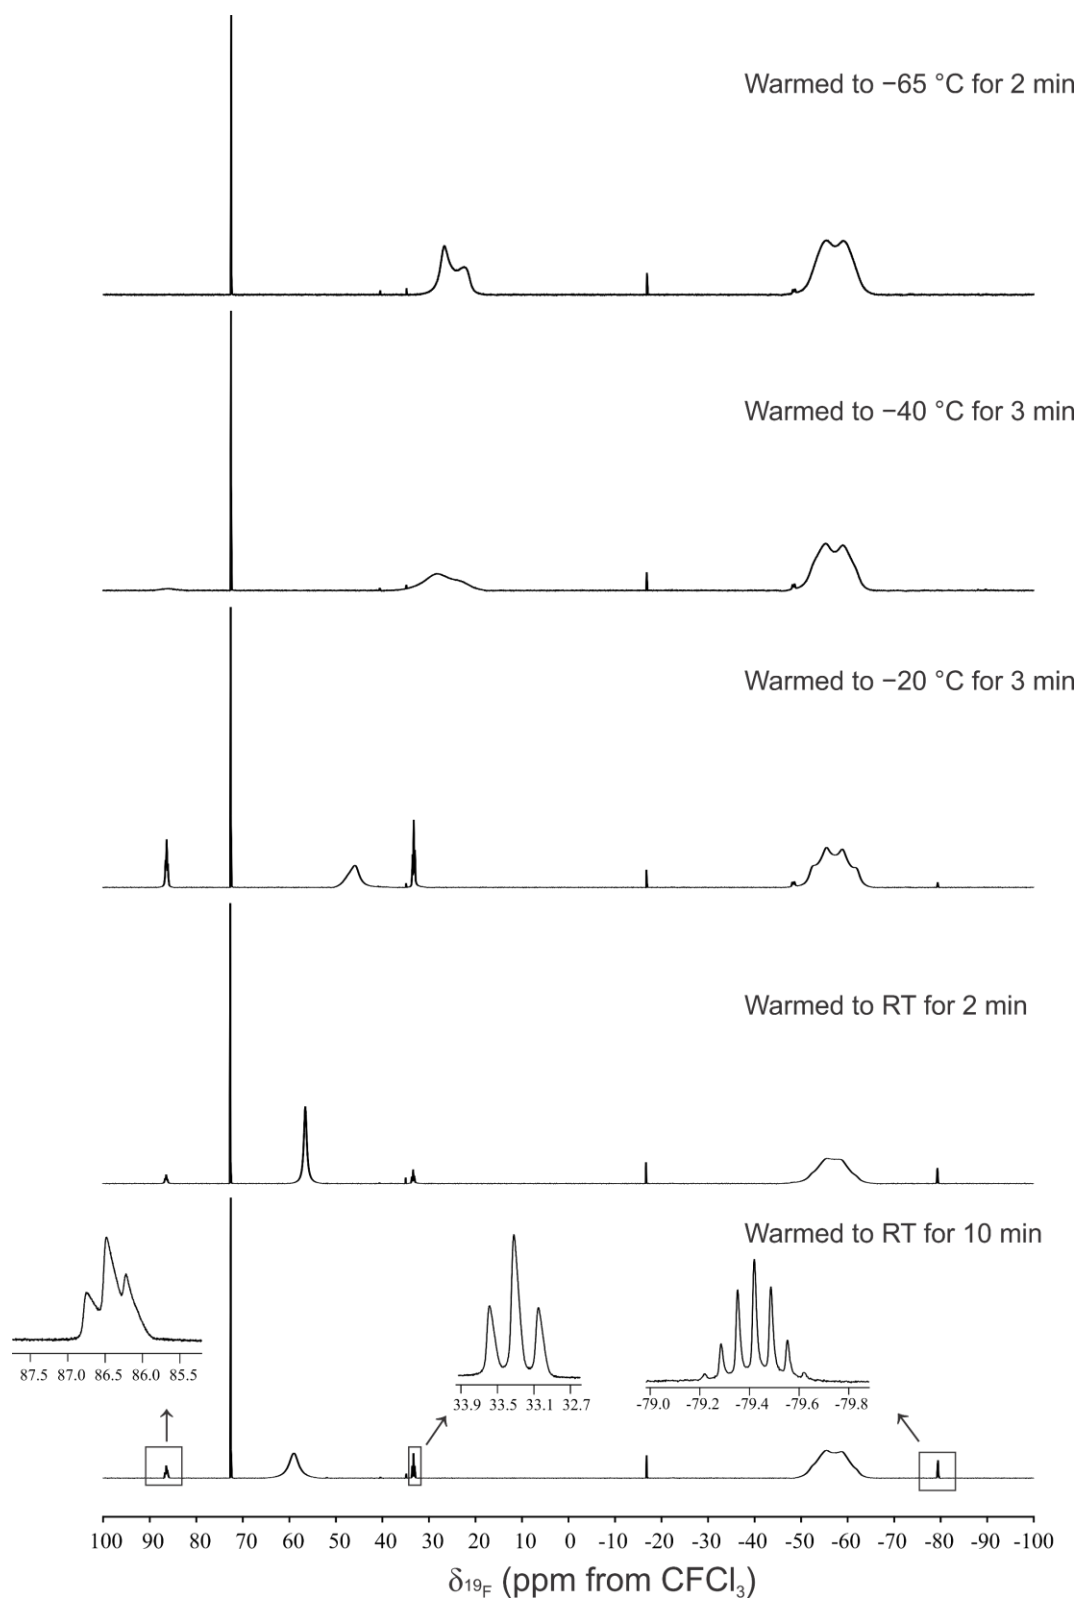

Figure 4.4  $^{19}\text{F}$  NMR spectra (282.40 MHz) showing the progress of the reaction of  $[\text{SF}_3][\text{AsF}_6]$  with three molar equivalents of acetone in  $\text{SO}_2$  at  $-70\text{ }^{\circ}\text{C}$ . All spectra were externally referenced to  $\text{CFCl}_3$  at RT.

Once the reaction was warmed to  $-20\text{ }^{\circ}\text{C}$ , two resonances of  $\text{SF}_4$  were observed as triplets (86.35 and 33.26 ppm) with scalar  $^2J(^{19}\text{F}-^{19}\text{F})$  coupling of 75.2 Hz, as well as a broad resonance at 45.9 ppm. The observation of the triplets may suggest  $\text{SF}_4$  is weakly interacting with acetone preventing exchange of the fluorine environments. When  $\text{SF}_4$  was dissolved in  $\text{SO}_2$ , broad singlets were observed at 85.9 ( $\text{F}_{\text{ax}}$ ) and 34.1 ppm ( $\text{F}_{\text{eq}}$ ), whereas, when  $\text{SF}_4$  was dissolved in excess acetone, sharp triplet resonances at 77.70 ( $\text{F}_{\text{ax}}$ ) and 30.53 ppm ( $\text{F}_{\text{eq}}$ ) were detected (Table 4.2). When  $\text{SF}_4$  was reacted with acetone in  $\text{SO}_2$ , in a 1:1 molar ratio, sharp triplet resonances were observed at 86.48 ( $\text{F}_{\text{ax}}$ ) and 33.32 ppm ( $\text{F}_{\text{eq}}$ ). Rapid exchange of the fluorine environments was most likely prevented through weak interactions with the Lewis base acetone, thus allowing the observation of the triplets as opposed to broad singlets. The broad resonance at 45.9 ppm, in the  $^{19}\text{F}$  NMR spectrum of the reaction, was likely associated with the presence of  $\text{SF}_4$  whose fluorine environments rapidly exchange with those of  $[\text{SF}_3]^+$ . This was confirmed by dissolving  $[\text{SF}_3][\text{AsF}_6]$  in  $\text{SO}_2$  and adding  $\text{SF}_4$  (approximate 1:1 molar ratio) which gave only one broad singlet at 44.8 ppm in the  $^{19}\text{F}$  NMR spectrum recorded at  $-70\text{ }^{\circ}\text{C}$  as a consequence of fast exchange between the fluorine environments of  $[\text{SF}_3]^+$  and  $\text{SF}_4$  (refer to Table 4.2). A very weak doublet was observed at 48.3 ppm from the dissociation of  $[\text{SF}_3][\text{AsF}_6]$  into  $\text{SF}_4$  and  $\text{AsF}_5\cdot\text{O}=\text{C}(\text{CH}_3)_2$  (refer to Chapter 6 for results regarding adducts of  $\text{AsF}_5$  with ketones).

At RT, the reaction turned a dark, deep red colour. The  $\text{SF}_4$  triplet resonances were slightly diminished and a broad singlet appeared at 56.5 ppm, attributed to rapidly exchanging  $\text{SF}_4$  and  $[\text{SF}_3]^+$  with an increased contribution from  $\text{SF}_4$ . Leaving the reaction at RT for 10 min resulted in this resonance (59.0 ppm) slightly decreasing in relative intensity with respect to  $[\text{AsF}_6]^-$  going from an integration of 2.4:6.0 to 1.9:6.0. This was followed by the appearance of a septet at  $-79.40$  ppm, albeit in small quantities, associated

with 2,2-difluoropropane (reported  $\delta(^{19}\text{F})$  of  $-81.5$  ppm),<sup>[8]</sup> a product of the deoxofluorination of acetone.

The progress of this reaction was also characterized using  $^1\text{H}$  NMR spectroscopy at  $-70$  °C (Figure 4.5), however, because of the complexity of this reaction, little information was obtained from the  $^1\text{H}$  NMR spectra. At  $-63$  °C the proton NMR spectrum showed three different acetone singlet resonances:  $[\text{SF}_3 \cdot \text{O}=\text{C}(\text{CH}_3)_2]^+$  (2.74 ppm),  $[\text{SF}_3 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_2]^+$  (2.58 ppm), and free acetone (2.55 ppm) (acetone in  $\text{SO}_2$  appears at 2.53 ppm). This is consistent with the  $^{19}\text{F}$  NMR spectrum, which showed both the 1:1 (26.74 ppm) and 1:2 (22.66 ppm) adducts of  $[\text{SF}_3]^+$  with acetone. Upon warming to RT for 10 min, no free acetone remained, and the main resonance was observed at 3.00 ppm along with a small amount ( $< 1\%$ ) of 2,2-difluoropropane (1.82 ppm).

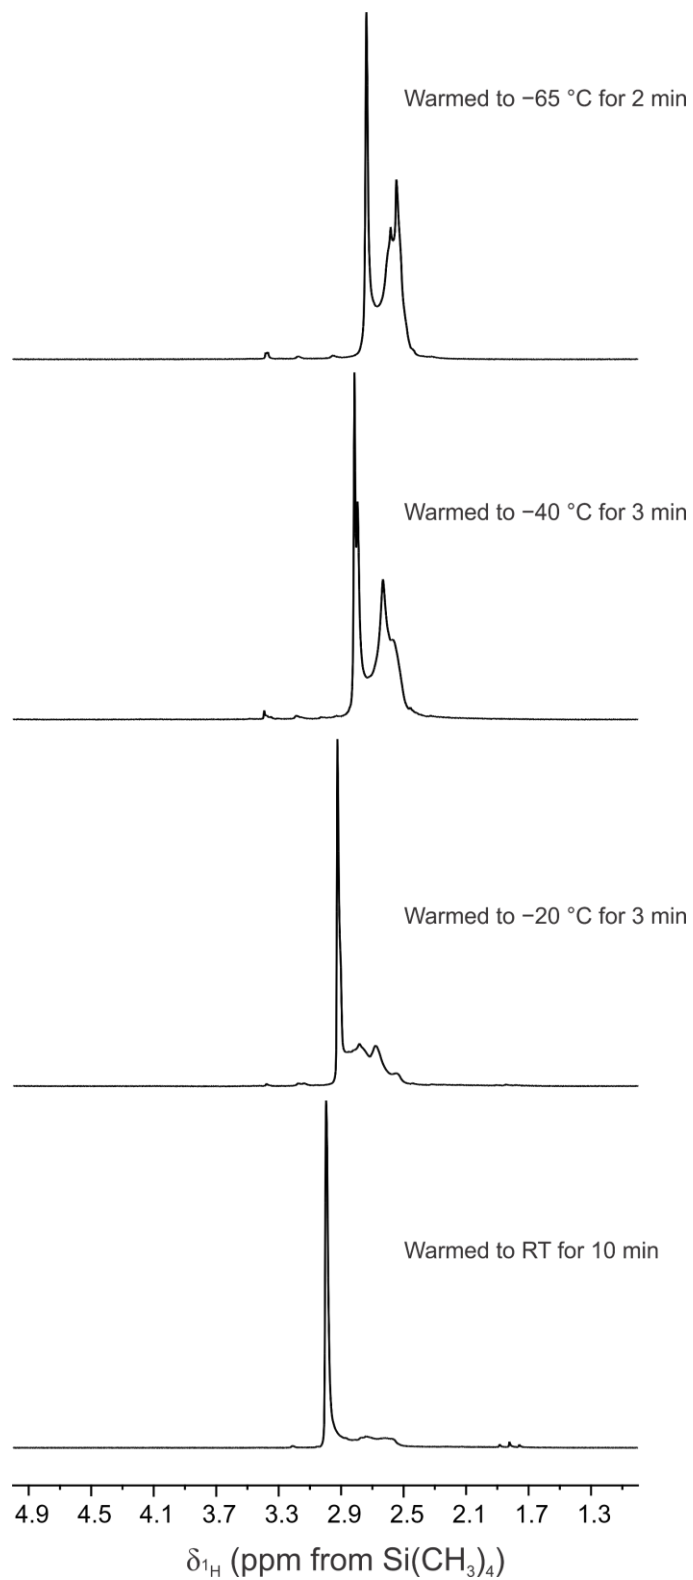

Figure 4.5  $^1\text{H}$  NMR spectra (300.13 MHz) showing the progress of the reaction of  $[\text{SF}_3][\text{AsF}_6]$  with three equivalents of acetone at  $-70^\circ\text{C}$  in  $\text{SO}_2$ . Spectra were externally referenced to  $\text{Si}(\text{CH}_3)_4$  at RT.

#### 4.2.4 [SF<sub>3</sub>][AsF<sub>6</sub>] and 2.5 Equivalents of Acetone in SO<sub>2</sub>

The reaction of 2.5 molar equivalents of acetone with [SF<sub>3</sub>][AsF<sub>6</sub>] in SO<sub>2</sub> resulted in a clear, colourless solution upon melting at -70 °C. The <sup>19</sup>F NMR spectra are depicted in Figure 4.6 and the chemical shifts and coupling constants are listed in Table 4.4. At -60 °C, a <sup>19</sup>F resonance appeared as a singlet at 21.26 ppm (Figure 4.5) which was assigned to the [SF<sub>3</sub>·{O=C(CH<sub>3</sub>)<sub>2</sub>}<sub>2</sub>]<sup>+</sup> cation. An additional weaker, broad peak at 28.5 ppm was assigned to the [SF<sub>3</sub>·O=C(CH<sub>3</sub>)<sub>2</sub>]<sup>+</sup> adduct, which is present likely as a result of insufficient mixing. The [AsF<sub>6</sub>]<sup>-</sup> anion has a <sup>19</sup>F resonance at -56.5 ppm, however, unlike when the reaction was performed in excess acetone, the electric field gradient about <sup>75</sup>As in these adducts causes quadrupolar relaxation of the <sup>75</sup>As (I = 3/2, 100%) nucleus such that the <sup>1</sup>J(<sup>19</sup>F-<sup>75</sup>As) coupling is partially quadrupolar collapsed. The [AsF<sub>6</sub>]<sup>-</sup> anion can share one contact with the [SF<sub>3</sub>·{O=C(CH<sub>3</sub>)<sub>2</sub>}<sub>2</sub>]<sup>+</sup> cation giving the sulfur of [SF<sub>3</sub>]<sup>+</sup> a coordination number of 6.

The colour began to change upon warming to -45 °C to a clear, faint red solution. The [SF<sub>3</sub>·{O=C(CH<sub>3</sub>)<sub>2</sub>}<sub>2</sub>]<sup>+</sup> cation was still present in solution at this temperature, however, an unidentified shoulder peak appeared at 21.9 ppm. Warming to -40 °C resulted in a resonance at 22.12 ppm with no shoulder peak. This may be the result of small amounts of SF<sub>4</sub> forming leading to exchange of the fluorine environments and a subsequent increase in the chemical shift. When the sample was warmed to -35 °C, the solution turned a dark orange/brown colour and the <sup>19</sup>F NMR spectrum showed the presence of two broad singlets at 86.5 (F<sub>ax</sub>) and 33.1 ppm (F<sub>eq</sub>) from the formation of SF<sub>4</sub>, and some remaining [SF<sub>3</sub>·{O=C(CH<sub>3</sub>)<sub>2</sub>}<sub>2</sub>]<sup>+</sup> cation (22.1 ppm). A dismutation reaction occurs where two

equivalents of  $[\text{SF}_3 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_2][\text{AsF}_6]$  yields  $\text{SF}_4$  and presumably  $[\text{SF}_2 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_2][\text{AsF}_6]_2$  (Equation 4.4).

Table 4.4 Selected  $^{19}\text{F}$  chemical shifts ( $\delta$ ) at  $-70\text{ }^\circ\text{C}$  for the reaction of  $[\text{SF}_3][\text{AsF}_6]$  with 2.5 molar equivalents of acetone in  $\text{SO}_2$ .

<sup>a</sup> Abbreviations: (s) singlet; (t) triplet; (sh) shoulder; (ax) axial; (eq) equatorial; (br) broad. <sup>b</sup> Quadrupolar broadened.

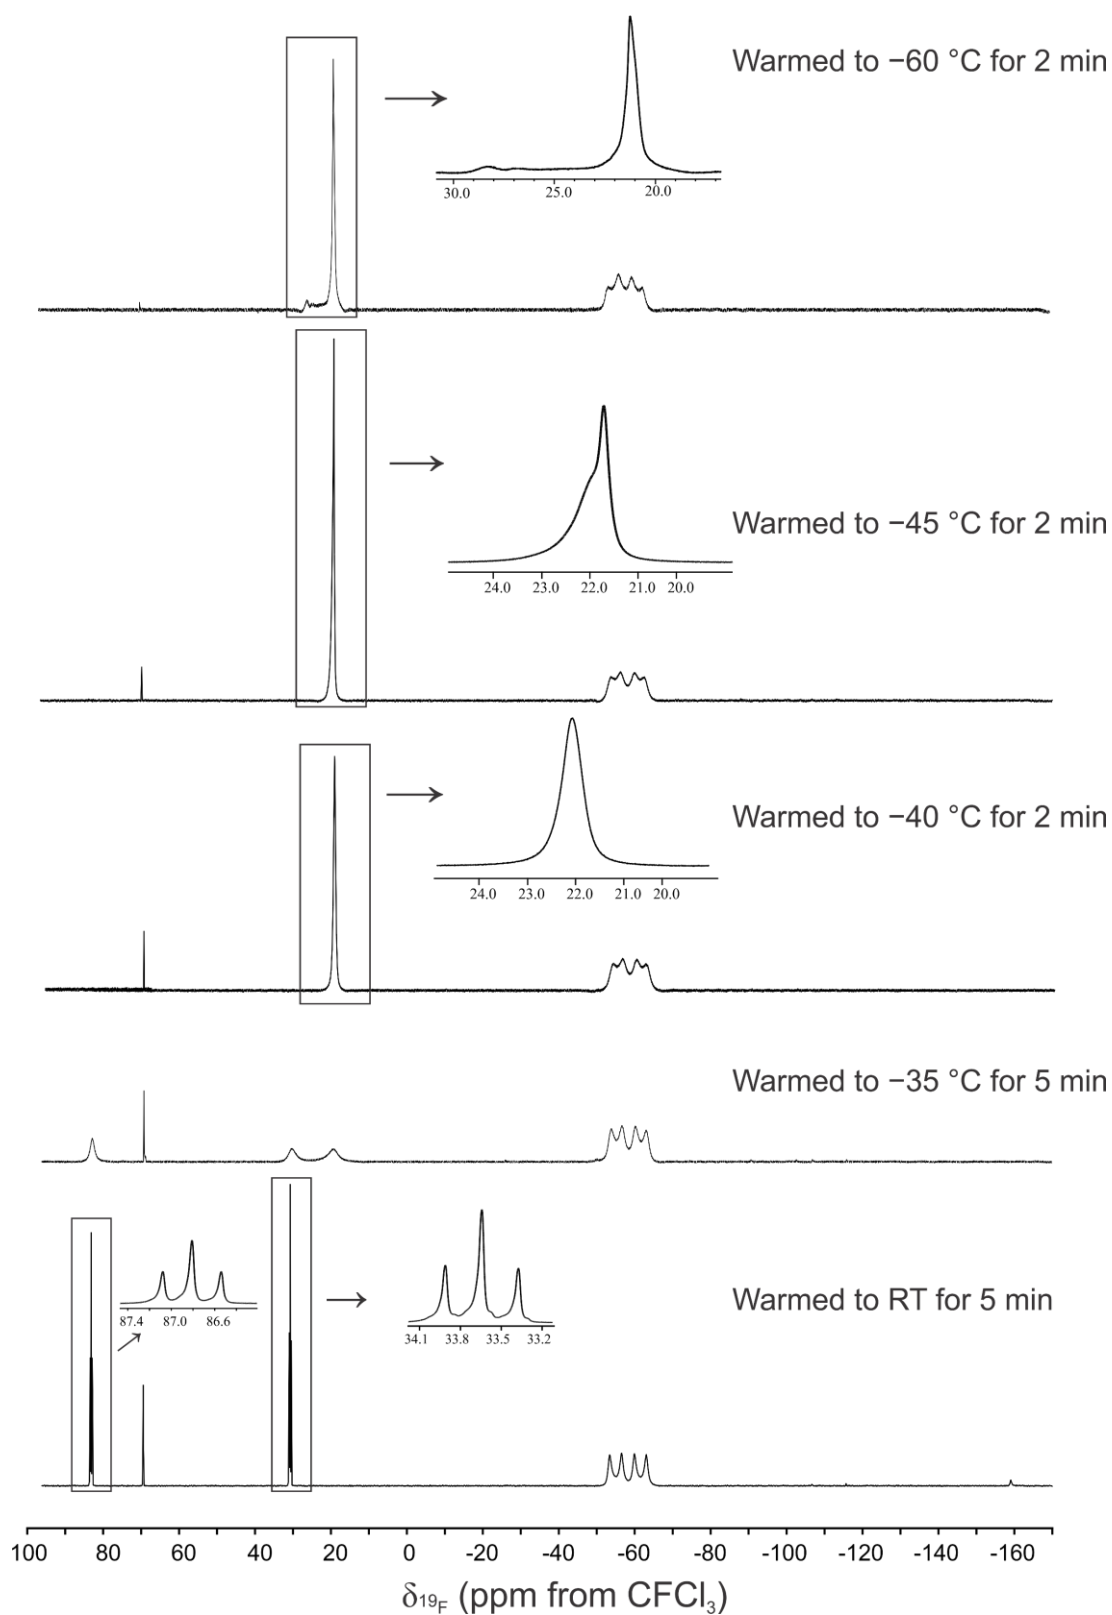

Figure 4.6  $^{19}\text{F}$  NMR spectra (282.40 MHz) showing the progress of the reaction of  $[\text{SF}_3][\text{AsF}_6]$  with 2.5 molar equivalents of acetone in  $\text{SO}_2$  at  $-70^\circ\text{C}$ . All spectra were externally referenced to  $\text{CFC1}_3$  at RT.

The dark orange/brown solution remained when warmed to RT. After 5 min at RT, the SF<sub>4</sub> signals became two sharp triplet <sup>19</sup>F resonances at 86.80 (F<sub>ax</sub>) and 33.64 ppm (F<sub>eq</sub>) with <sup>2</sup>J(<sup>19</sup>F–<sup>19</sup>F) coupling of 76.1 Hz. A small amount of HF was detected at –158.8 ppm as a singlet, but otherwise no deoxofluorination products, such as 2,2-difluoropropane, were observed upon warming the reaction to RT. While <sup>1</sup>H NMR spectroscopy was acquired, no additional information was obtained. The singlet resonance in the <sup>1</sup>H NMR spectrum was the only signal observed which gradually shifted to higher frequencies upon warming the reaction (2.49 ppm at –56 °C; 2.80 ppm at –35 °C; 2.97 at RT for 5 min). The single resonance indicates fast chemical exchange. The increasing chemical shift over time likely resulted from an increase in the concentration of strongly adducted acetone or the unidentified paramagnetic species interacting with acetone.

#### **4.2.5 [SF<sub>3</sub>][AsF<sub>6</sub>] and One Equivalent of Acetone in SO<sub>2</sub>**

The reaction between [SF<sub>3</sub>][AsF<sub>6</sub>] and one equivalent of acetone in SO<sub>2</sub> gave unexpected results. Upon melting at –70 °C, a clear, colourless solution was formed. The <sup>19</sup>F NMR spectra are depicted in Figure 4.7 and the chemical shifts and coupling constants are listed in Table 4.5.

Table 4.5 Selected  $^{19}\text{F}$  chemical shifts ( $\delta$ ) at  $-70\text{ }^{\circ}\text{C}$  for the reaction of  $[\text{SF}_3][\text{AsF}_6]$  with one molar equivalent of acetone in  $\text{SO}_2$ .

<sup>a</sup> Abbreviations: (s) singlet; (sept) septet; (m) multiplet; (ax) axial; (eq) equatorial; (sh) shoulder; (br) broad. <sup>b</sup> Quadrupolar broadened. <sup>c</sup> Sample contained two phases due to difficulty mixing. <sup>d</sup>  $^1\Delta^{19}\text{F}(^{34}/^{32}\text{S}) = 0.06$  ppm. <sup>e</sup>  $^3J(^{19}\text{F}-^1\text{H}) = 18.9$  Hz, yield ca. 3%.

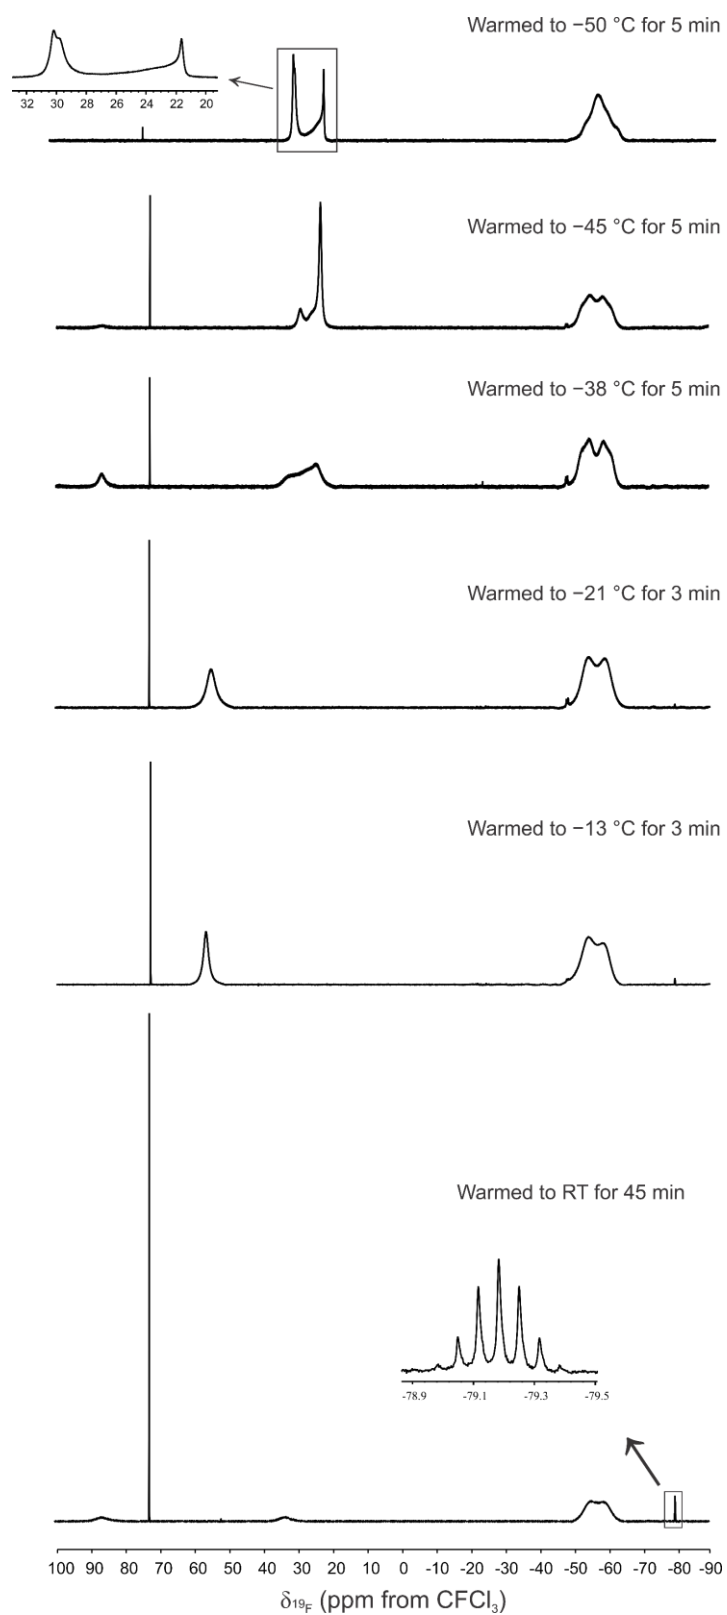

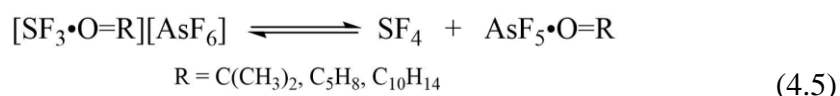

Figure 4.7  $^{19}\text{F}$  NMR spectra (282.40 MHz) showing the progress of the reaction of  $[\text{SF}_3][\text{AsF}_6]$  with acetone in  $\text{SO}_2$  at  $-70\text{ }^{\circ}\text{C}$  in a 1:1 molar ratio. All spectra were externally referenced to  $\text{CFC1}_3$  at RT.

At  $-50\text{ }^{\circ}\text{C}$ , three different  $[\text{SF}_3]^+$  species were present: free  $[\text{SF}_3]^+$  (30.17 ppm),  $[\text{SF}_3\cdot\text{O}=\text{C}(\text{CH}_3)_2]^+$  (shoulder at 29.8 ppm), and  $[\text{SF}_3\cdot\{\text{O}=\text{C}(\text{CH}_3)_2\}_2]^+$  (21.62 ppm). The likely cause of multiple  $[\text{SF}_3]^+$ -species is a result of the difficulties in sufficiently mixing the solution to give a homogeneous mixture while maintaining a stable low temperature. The  $[\text{AsF}_6]^-$  anion appeared at  $-56.0$  ppm as a quadrupolar collapsed multiplet where no  $^1J(^{19}\text{F}-^{75}\text{As})$  coupling was observed (Figure 4.7). At  $-45\text{ }^{\circ}\text{C}$  the  $[\text{SF}_3]^+$  cation was presumably adducted to two acetone molecules (23.48 ppm), however, a broad singlet at 29.3 ppm suggested that a small amount of the 1:1 adduct is also present in solution. A very weak, broad  $^{19}\text{F}$  resonance characteristic of the axial fluorine atoms in  $\text{SF}_4$  was detected at 87 ppm. When the reaction was warmed to  $-38\text{ }^{\circ}\text{C}$ , the sample began turning to a dark red colour and the broad singlet  $^{19}\text{F}$  resonances at 86.7 and 32.3 ppm indicated the formation of  $\text{SF}_4$ . Interestingly, a doublet at  $-47.9$  ppm was also observed indicative of the formation of  $\text{AsF}_5\cdot\text{O}=\text{C}(\text{CH}_3)_2$  due to the equilibrium between  $[\text{SF}_3][\text{AsF}_6]$  and  $\text{SF}_4/\text{AsF}_5$  (Equation 4.5), induced by the presence of one equivalent of acetone and strong  $\text{F}_3\text{S}^+ \cdots \text{FAsF}_5^-$  interactions (see Chapter 6 for results regarding adducts of ketones with  $\text{AsF}_5$ ).

Unlike the reaction with two equivalents of acetone, or excess acetone, warming to higher temperatures ( $-21$  and  $-13\text{ }^{\circ}\text{C}$ ) resulted in observation of  $\text{SF}_4$  as a broad singlet at 55.03 ppm (56.86 at  $-13\text{ }^{\circ}\text{C}$ ) as a result of exchanges with  $[\text{SF}_3]^+$ , similar to the one exhibited in the reaction with three equivalents of acetone, as well as a small amount of the  $\text{AsF}_5\cdot\text{O}=\text{C}(\text{CH}_3)_2$  adduct ( $-47.9$  ppm). At  $-13\text{ }^{\circ}\text{C}$ , the integration ratio between  $\text{SOF}_2$  (72.90 ppm), the  $\text{SF}_4/[\text{SF}_3]^+$  resonance (56.86 ppm), and  $[\text{AsF}_6]^-$  ( $-56.6$  ppm), gave a

0.2:4.0:14.2 ratio (or 0.1:2.0:7.1). The integration of 0.2 for  $\text{SOF}_2$  suggests that deoxofluorination of the carbonyl group had not occurred to any significant extent.

Warming the sample to RT for 45 min resulted in weak broad singlets at 87 and 34 ppm from  $\text{SF}_4$ , as well as a septet at  $-79.2$  ppm with a scalar  $^3J(^{19}\text{F}-^1\text{H})$  coupling of 18.9 Hz. The  $^1\text{H}$  NMR spectrum (Figure 4.8) of the reaction at this temperature contained an intense singlet at 3.14 ppm, associated with acetone, and a less intense triplet resonance at 1.93 ppm ( $^3J(^{19}\text{F}-^1\text{H}) = 18.9$  Hz), likely from 2,2-difluoropropane ( $\delta(^1\text{H}) = 1.37$  ppm;  $^3J(^{19}\text{F}-^1\text{H}) = 19$  Hz).<sup>[8]</sup> The  $^1\text{H}$  NMR spectrum of a solution of acetone in  $\text{SO}_2$  at  $-70$  °C shows a singlet at 2.53 ppm; the acetone signal in the sample warmed to RT is now shifted to a higher frequency (3.14 ppm) indicating electron density has been removed from the  $\text{CH}_3$  groups, possibly through adducted acetone.

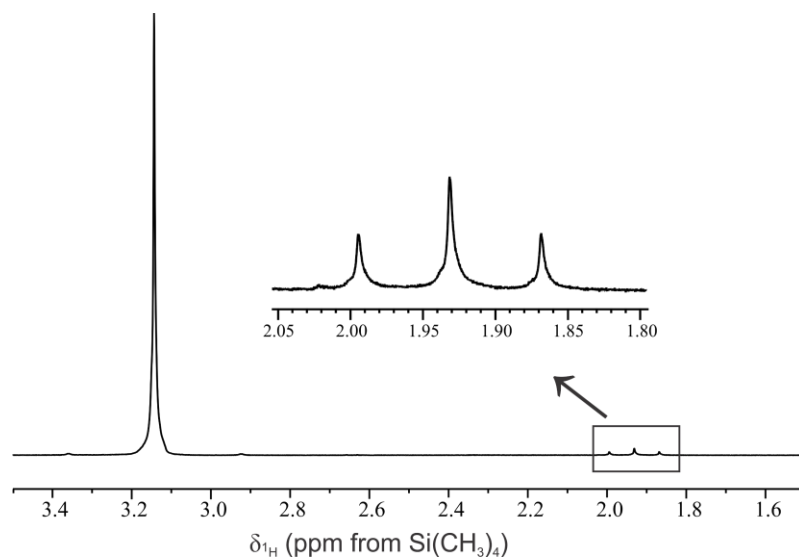

Figure 4.8  $^1\text{H}$  NMR spectrum (300.13 MHz) at  $-70$  °C showing the reaction of  $[\text{SF}_3][\text{AsF}_6]$  with acetone in  $\text{SO}_2$  in a 1:1 molar ratio after having been warmed to RT for 45 min. Externally referenced to  $\text{Si}(\text{CH}_3)_4$  at RT.

#### 4.2.6 [SF<sub>3</sub>][AsF<sub>6</sub>] and Two Equivalents of Cyclopentanone in SO<sub>2</sub>

Reacting [SF<sub>3</sub>][AsF<sub>6</sub>] with 2.2 molar equivalents of cyclopentanone in SO<sub>2</sub> at −70 °C resulted in a clear colourless solution. The <sup>19</sup>F NMR spectra are depicted in Figure 4.9 and the chemical shifts and coupling constants are listed in Table 4.6.

Table 4.6 Selected <sup>19</sup>F chemical shifts (δ) at −70 °C for the reaction of [SF<sub>3</sub>][AsF<sub>6</sub>] with 2.2 molar equivalents of cyclopentanone in SO<sub>2</sub>.

<sup>a</sup> Abbreviations: (s) singlet; (d) doublet; (ax) axial; (eq) equatorial; (sh) shoulder

<sup>b</sup> Unidentified resonance at −17 ppm, likely an impurity. <sup>c</sup> Quadrupolar broadened.

<sup>d</sup> <sup>1</sup>Δ<sup>19</sup>F(<sup>34/32</sup>S) = 0.061 ppm.

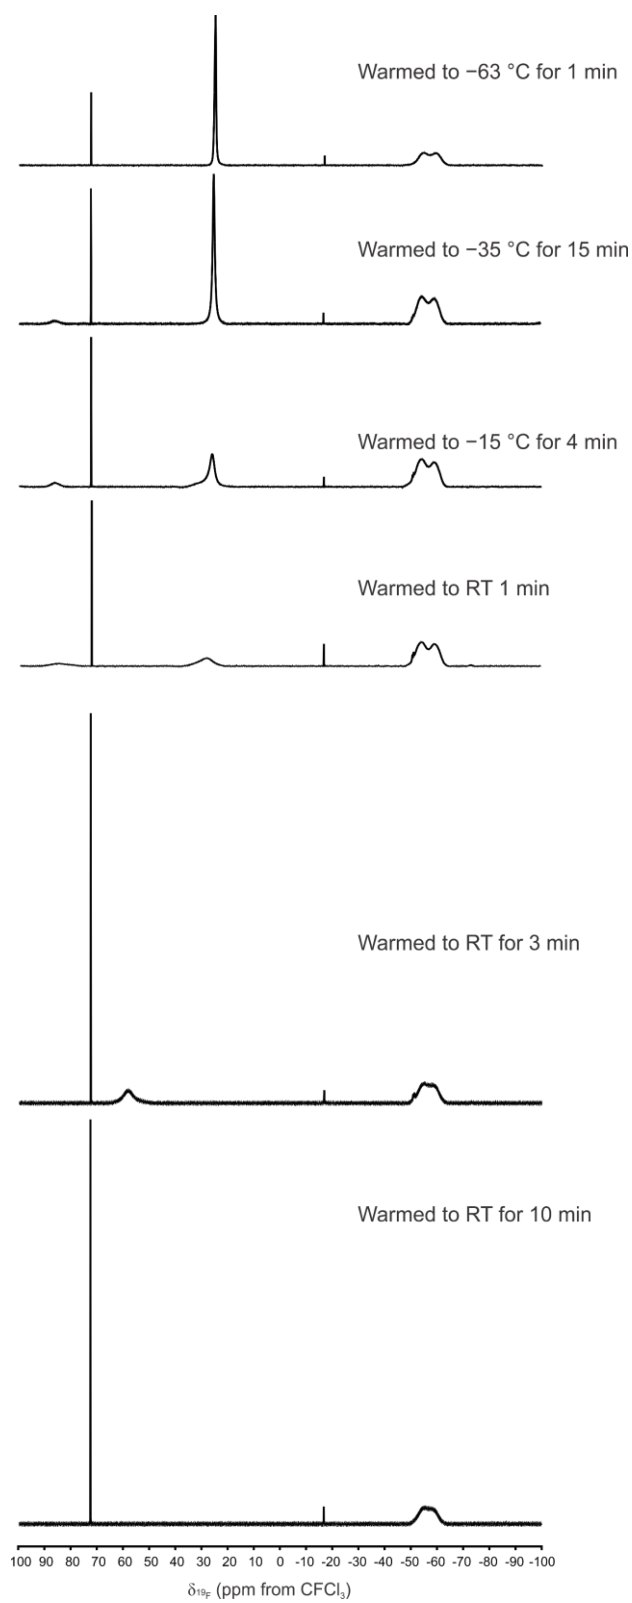

Figure 4.9  $^{19}\text{F}$  NMR spectra (282.40 MHz) showing the progress of the reaction of  $[\text{SF}_3][\text{AsF}_6]$  with 2.2 molar equivalents of cyclopentanone in  $\text{SO}_2$  at  $-70^\circ\text{C}$ . All spectra were externally referenced to  $\text{CFCl}_3$  at RT.

When the reaction was first warmed to  $-63\text{ }^{\circ}\text{C}$ , the 1:2 adduct between  $[\text{SF}_3]^+$  and cyclopentanone was formed (25.04 ppm). At  $-35\text{ }^{\circ}\text{C}$  the solution turned a clear orange colour and the  $^{19}\text{F}$  NMR spectrum showed the  $[\text{SF}_3\cdot(\text{O}=\text{C}_5\text{H}_8)_2]^+$  cation (25.47 ppm) to be stable, as well as a weak broad resonance at 86.4 ppm revealing the formation of  $\text{SF}_4$ . Unlike the acetone system, the  $[\text{SF}_3\cdot(\text{O}=\text{C}_5\text{H}_8)_2]^+$  adduct (26.13 ppm) was still detected in solution at  $-15\text{ }^{\circ}\text{C}$ . The chemical shift increased slightly due to chemical exchange of the fluorine atoms with those from some of the  $\text{SF}_4$ . The decrease in the intensity of the signal was accompanied by an increase in the amount of non-exchanging  $\text{SF}_4$  (86.7 and 32.6 ppm). Three different  $^{19}\text{F}$  NMR spectra were collected at  $-70\text{ }^{\circ}\text{C}$  after leaving the reaction at RT for different lengths of time. After the first minute, the sample turned a dark red colour and the concentration of the 1:2 adduct (28.7 ppm) in solution had significantly decreased. After 3 min, a new resonance appeared at 58.6 ppm resulting from exchange between the fluorine environments of  $\text{SF}_4$  and  $[\text{SF}_3]^+$ . The weak resonance at  $-50.9$  ppm is associated with a small concentration of the  $\text{AsF}_5\cdot\text{O}=\text{C}_5\text{H}_8$  adduct resulting from the dissociation of  $[\text{SF}_3][\text{AsF}_6]$  into  $\text{SF}_4$  and  $\text{AsF}_5$  (refer to Equation 4.5). After 10 min at RT, the only resonances remaining were the  $[\text{AsF}_6]^-$  ( $-56.8$  ppm) and  $\text{SOF}_2$  (72.71 ppm). No signs of deoxofluorination products were detected (i.e., 1,1-difluorocyclopentane), however, going from 1 min to 10 min at RT resulted in an increase in the amount of  $\text{SOF}_2$  (integration  $\text{SOF}_2:[\text{AsF}_6]^-$  at RT for 1 min, 0.3:12; RT for 10 min, 0.6:12) suggesting some kind of deoxofluorination occurred. It is possible the cationic species in this system is a radical which would not be observed in the NMR spectrum and could account for the solution becoming a dark red colour.

The  $^1\text{H}$  NMR spectra were also recorded for the  $\text{SO}_2$  solutions at  $-70\text{ }^{\circ}\text{C}$  and are depicted in Figure 4.10 with the chemical shifts listed in Table 4.7. A gradual increase in

the chemical shift was observed upon warming the reaction from  $-63\text{ }^{\circ}\text{C}$  to RT. Unadducted cyclopentanone in  $\text{SO}_2$  at  $-70\text{ }^{\circ}\text{C}$  gives rise to two resonances at 2.40 and 2.16 ppm. The adducted cyclopentanone, in a 1:2 ratio, gave rise to two resonances at 2.80 and 2.32 ppm at  $-63\text{ }^{\circ}\text{C}$ . Only one set of signals were observed due to the fast exchange of the adducted and non-adducted cyclopentanone. The increase in frequency from non-adducted cyclopentanone was a consequence of the highly Lewis acidic  $[\text{SF}_3]^+$  withdrawing electron density from the  $\text{C}=\text{O}$  group and, subsequently, the 5-membered carbon ring of cyclopentanone. Once the reaction was at RT for 5 min the resonances were shifted to even higher frequencies (3.18 and 2.49 ppm) possibly resulting from the interaction with a paramagnetic species or fast chemical exchange of a strongly adducted cyclopentanone.

Table 4.7  $^1\text{H}$  chemical shifts ( $\delta$ ) at  $-70\text{ }^{\circ}\text{C}$  for the reaction of  $[\text{SF}_3][\text{AsF}_6]$  with 2.2 molar equivalents of cyclopentanone in  $\text{SO}_2$  (referenced to  $\text{Si}(\text{CH}_3)_4$  at RT).

Reaction Temperature ( $^{\circ}\text{C}$ )	Chemical Shift (ppm)
$-63$	2.80, 2.32
$-35$	2.81, 2.30
$-15$	2.90, 2.35
RT for 1 min	3.06, 2.44
RT for 5 min	3.18, 2.49

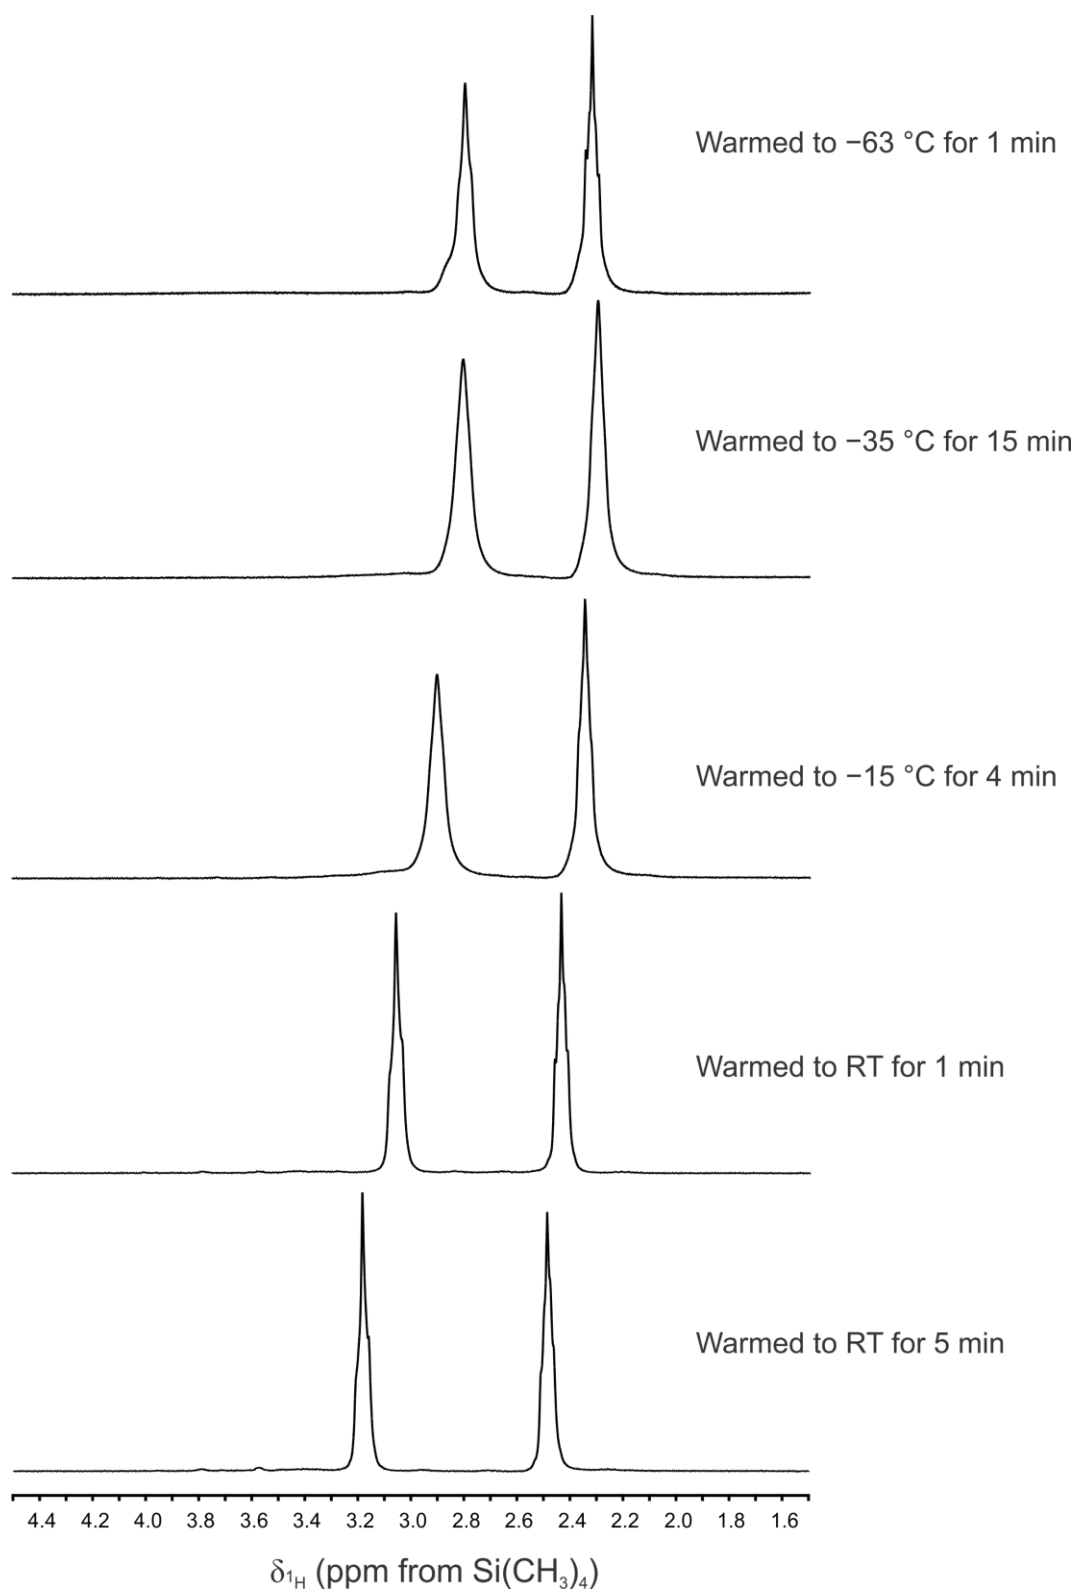

Figure 4.10  $^1\text{H}$  NMR spectra (300.13 MHz) showing the progress of the reaction of  $[\text{SF}_3][\text{AsF}_6]$  with 2.2 molar equivalents of cyclopentanone in  $\text{SO}_2$  at  $-70\text{ }^\circ\text{C}$ . All spectra were externally referenced to  $\text{Si}(\text{CH}_3)_4$  at RT.

#### 4.2.7 [SF<sub>3</sub>][AsF<sub>6</sub>] and One Equivalent of Cyclopentanone in SO<sub>2</sub>

The reaction of [SF<sub>3</sub>][AsF<sub>6</sub>] with 1.4 molar equivalent of cyclopentanone in SO<sub>2</sub> at -70 °C resulted in a clear colourless solution. The <sup>19</sup>F NMR spectra are depicted in Figure 4.11 and the chemical shifts and coupling constants are listed in Table 4.8. At this temperature, the 1:1 adduct between [SF<sub>3</sub>]<sup>+</sup> and cyclopentanone was formed (31.59 ppm) which is somewhat lower in frequency to [SF<sub>3</sub>][AsF<sub>6</sub>] in SO<sub>2</sub> (32.91 ppm). The resonance of [AsF<sub>6</sub>]<sup>-</sup> (-56.6 ppm) was observed as a quadrupolar collapsed broad singlet due to the relatively large electric field gradient about the <sup>75</sup>As nucleus (I = 3/2, 100%) compared to the 1:2 adduct where some <sup>1</sup>J(<sup>19</sup>F-<sup>75</sup>As) coupling could be detected (signals were overlapping and no information could be obtained). The fluorine ligands of [AsF<sub>6</sub>]<sup>-</sup> likely share upwards of two contacts with the sulfur of [SF<sub>3</sub>]<sup>+</sup>, which can have a coordination number of 6, resulting in a distorted octahedral geometry and a broad singlet that is quadrupolar collapsed.

Table 4.8 Selected  $^{19}\text{F}$  chemical shifts ( $\delta$ ) at  $-70\text{ }^{\circ}\text{C}$  for the reaction of  $[\text{SF}_3][\text{AsF}_6]$  with 1.4 molar equivalent of cyclopentanone in  $\text{SO}_2$ .

<sup>a</sup> Abbreviations: (s) singlet; (d) doublet; (quin) quintet; (ax) axial; (eq) equatorial.  
<sup>b</sup>  $^1\Delta^{19}\text{F}(^{34/32}\text{S}) = 0.061\text{ ppm}$ . <sup>c</sup> Quadrupolar broadened, no  $^1J(^{75}\text{As}-^{19}\text{F})$  coupling observed.

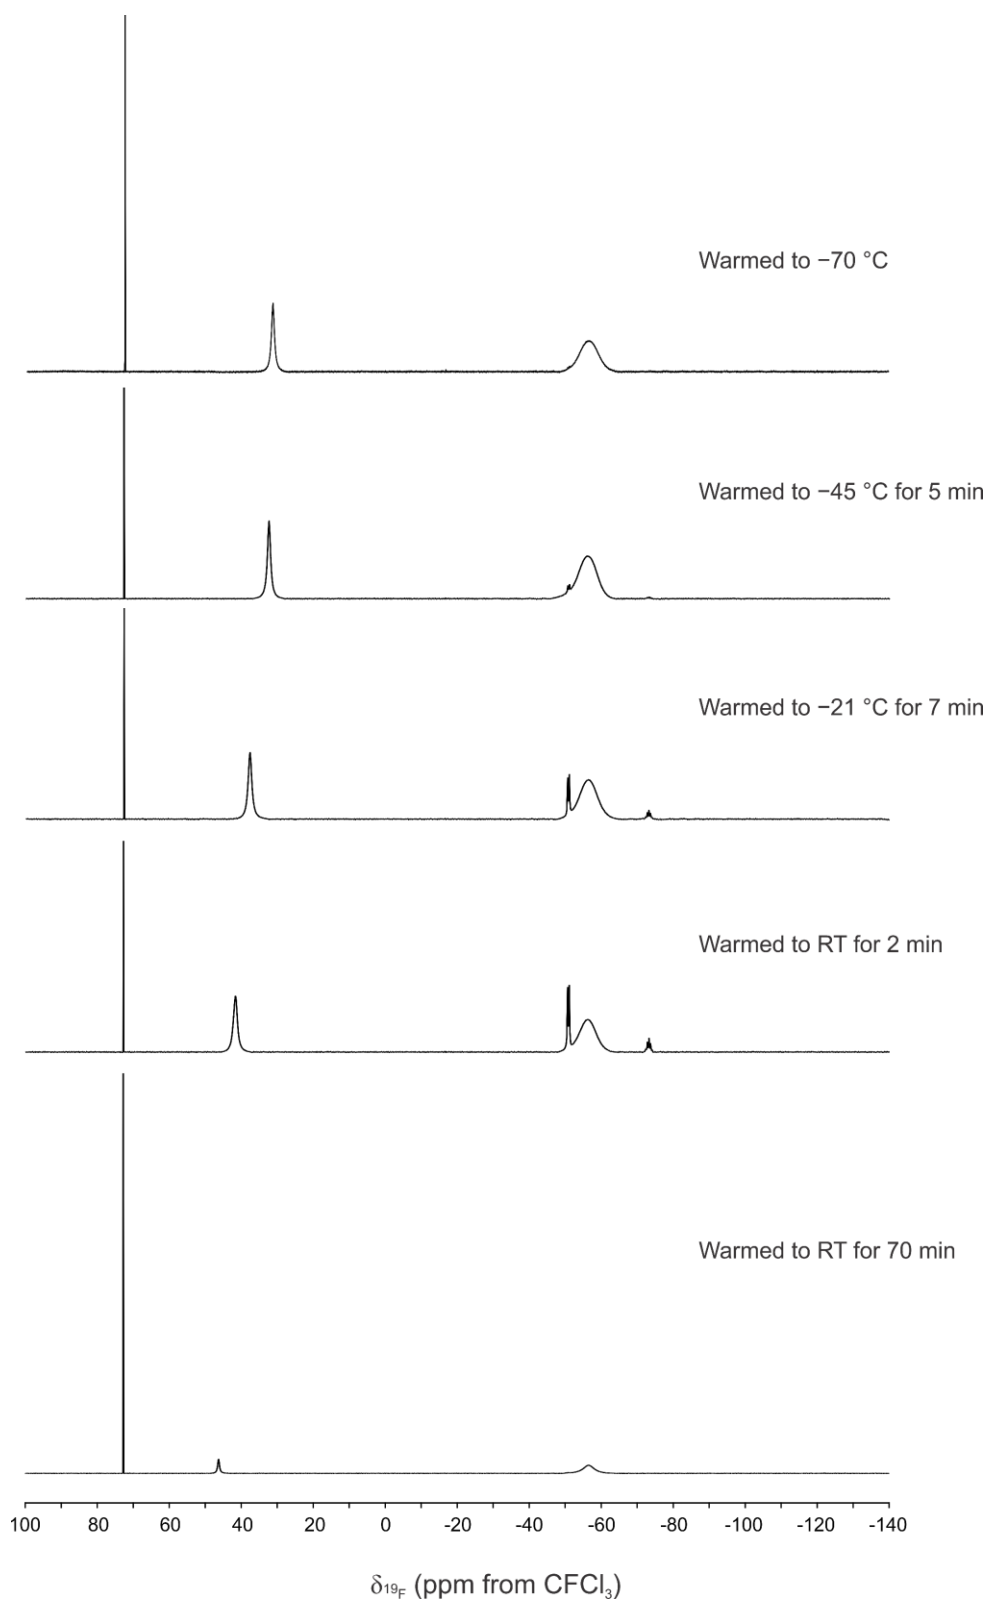

Figure 4.11  $^{19}\text{F}$  NMR spectra (282.40 MHz) showing the progress of the reaction of  $[\text{SF}_3][\text{AsF}_6]$  with 1.4 molar equivalents of cyclopentanone in  $\text{SO}_2$  at  $-70^\circ\text{C}$ . All spectra were externally referenced to  $\text{CFCl}_3$  at RT.

Upon warming this reaction to  $-45\text{ }^{\circ}\text{C}$ , a pale red solution formed. The  $[\text{SF}_3\cdot\text{O}=\text{C}_5\text{H}_8]^+$  resonance was slightly shifted to 32.46 ppm, likely due to exchange with some  $\text{SF}_4$  being formed, and the  $\text{AsF}_5\cdot\text{O}=\text{C}_5\text{H}_8$  adduct was detected as a doublet resonance at  $-50.80\text{ ppm}$  ( $F_{\text{eq}}$ ). At  $-21\text{ }^{\circ}\text{C}$  the solution remained a pale red colour. The doublet resonance of  $\text{AsF}_5\cdot\text{O}=\text{C}_5\text{H}_8$  increased in intensity and the corresponding quintet was also detected ( $F_{\text{ax}}$  at  $-73.17\text{ ppm}$ ;  $^2J(^{19}\text{F}-^{19}\text{F}) = 125\text{ Hz}$ ). When the reaction was allowed to warm to RT for 2 min, the clear pale red coloured solution remained and more of the  $\text{AsF}_5\cdot\text{O}=\text{C}_5\text{H}_8$  adduct was formed. The  $[\text{SF}_3][\text{AsF}_6]$  salt undergoes an equilibrium reaction to form  $\text{SF}_4$  and  $\text{AsF}_5$  in the presence of one equivalent of cyclopentanone (see Equation 4.5), similar to the 1:1 adduct of  $[\text{SF}_3]^+$  and acetone (refer to Section 4.2.5). At these higher temperatures, and upon forming the  $\text{AsF}_5\cdot\text{O}=\text{C}_5\text{H}_8$  adduct, more  $\text{SF}_4$  is made which forms a second equilibrium involving the dissociation of  $[\text{SF}_3\cdot\text{O}=\text{C}_5\text{H}_8]^+$  to free  $[\text{SF}_3]^+$ . As the reaction was warmed to higher temperatures, the concentration of  $\text{SF}_4$  increased and, therefore, less  $[\text{SF}_3]^+$  is in solution resulting in the resonances being shifted to higher frequencies (37.78 ppm at  $-21\text{ }^{\circ}\text{C}$  and 41.67 ppm at RT for 2 min). Rapid exchange of the fluorine environments of  $[\text{SF}_3]^+$  and  $\text{SF}_4$  results from the open coordination sites around  $[\text{SF}_3]^+$  leading to a broadened signal. Based on the integration ratios between  $\text{AsF}_5$  and  $[\text{AsF}_6]^-$ , three equivalents of  $[\text{AsF}_6]^-$  were present for every one equivalent of  $\text{AsF}_5$ . Leaving this reaction for 70 min at RT resulted in a deep, dark red coloured solution where nearly all  $\text{AsF}_5\cdot\text{O}=\text{C}_5\text{H}_8$  had dissociated and only the resonances for the  $[\text{SF}_3]^+/\text{SF}_4$  equilibrium (46.42 ppm),  $[\text{AsF}_6]^-$  anion ( $-56.4\text{ ppm}$ ), and a significantly increased amount of  $\text{SOF}_2$  (72.78 ppm) remained with an integration ratio of 3.8:12.0:2.0. The disappearance of the  $\text{AsF}_5\cdot\text{O}=\text{C}_5\text{H}_8$  adduct and increase in  $\text{SOF}_2$  suggests  $\text{AsF}_5\cdot\text{O}=\text{C}_5\text{H}_8$  may be involved in deoxofluorination, as previously stated by Smith et al.<sup>[9]</sup>

The  $^1\text{H}$  NMR spectra were collected at  $-70\text{ }^\circ\text{C}$  and are shown in Figure 4.12 and the chemical shifts are listed in Table 4.9. The resonance of the  $[\text{SF}_3\cdot\text{O}=\text{C}_5\text{H}_8]^+$  cation (3.12 and 2.49 ppm) at  $-70\text{ }^\circ\text{C}$  showed no significant change until the reaction was warmed to  $-21\text{ }^\circ\text{C}$ , and subsequently RT for 2 min, where the  $\text{AsF}_5\cdot\text{O}=\text{C}_5\text{H}_8$  was detected at 3.49, 3.40, and 2.57 ppm. The presence of only two signals at  $-70\text{ }^\circ\text{C}$  is a result of fast exchange between adducted and non-adducted cyclopentanone with  $[\text{SF}_3]^+$ . The  $\text{AsF}_5\cdot\text{O}=\text{C}_5\text{H}_8$  adduct is not undergoing fast exchange and appears as separate signals at 3.49, 3.40, and 2.57 ppm after being at RT for 2 min. Leaving the reaction at RT for 70 min resulted in the chemical shifts moving to higher frequencies (3.61, 2.66 ppm) and the appearance of a signal at 14.69 ppm, characteristic of the  $[\text{HO}=\text{C}_5\text{H}_8]^+$  cation. The relative integrations of the resonances at 14.69, 3.61, and 2.66 ppm were 1.0:4.0:4.3, suggesting that all of the cyclopentanone was protonated. The origin of the proton is currently not understood; quantitative hydrolysis of  $\text{SF}_4$  from accidental water is highly unlikely. No deoxofluorination products (i.e., 1,1-difluorocyclopentane) were observed in the  $^{19}\text{F}$  or  $^1\text{H}$  NMR spectra.

Table 4.9  $^1\text{H}$  chemical shifts ( $\delta$ ) at  $-70\text{ }^\circ\text{C}$  for the reaction of  $[\text{SF}_3][\text{AsF}_6]$  with 1.4 molar equivalents of cyclopentanone in  $\text{SO}_2$  (referenced to  $\text{Si}(\text{CH}_3)_4$  at RT).

#### 4.2.8 [SF<sub>3</sub>][AsF<sub>6</sub>] and Two Equivalents of 2-Adamantanone in SO<sub>2</sub>

The reaction of [SF<sub>3</sub>][AsF<sub>6</sub>] with two molar equivalents of 2-adamantanone in SO<sub>2</sub> was carried out at –70 °C and resulted in the precipitation of a white powder. In a separate reaction, attempts to characterize the white precipitate were made by removing the SO<sub>2</sub> under dynamic vacuum at –60 °C, however, a light brown powder remained which was unidentifiable by Raman spectroscopy due to large fluorescence. The insolubility of the powder in SO<sub>2</sub> at low temperatures required the NMR sample to be quickly warmed to –10 °C (ca. 1 min) until the reaction product dissolved resulting in a clear yellow solution. In doing so, gas formation was observed and presumed to be SF<sub>4</sub>. This was confirmed after collecting the <sup>19</sup>F NMR spectrum at –40 °C (Figure 4.13) where broad singlet resonances at 87.3 and 31.8 ppm were detected characteristic of SF<sub>4</sub> (Table 4.10). While <sup>1</sup>H NMR spectroscopy was also acquired, the spectra provided little information in determining the exact nature of the products of this reaction as a result many overlapping signals of 2-adamantanone (Figure 4.14). The presence of the smaller set of signals from 4.20 to 3.15 ppm might be an indication that a small amount of adamantyl cation was formed, although no evidence for the 2-fluoroadamantyl cation was observed in the <sup>19</sup>F NMR spectra.

Table 4.10 Selected  $^{19}\text{F}$  chemical shifts ( $\delta$ ) at  $-40\text{ }^{\circ}\text{C}$  for the reaction of  $[\text{SF}_3][\text{AsF}_6]$  with two molar equivalents of 2-adamantanone in  $\text{SO}_2$ .

Compound	Chemical Shift (ppm) <sup>a</sup>	$^2J(^{19}\text{F}-^{19}\text{F})$ (Hz)
<i>Reaction at <math>-10\text{ }^{\circ}\text{C}</math> for 1 min</i>		
$\text{SF}_4$	87.3 ( $\text{F}_{\text{ax}}$ , s, br) 31.8 ( $\text{F}_{\text{eq}}$ , sh)	--
$\text{SOF}_2$	73.32 (s) <sup>b</sup>	--
$[\text{SF}_3 \cdot (\text{O}=\text{C}_{10}\text{H}_{14})_2]^+$	25.6 (s, br)	--
$\text{AsF}_5 \cdot \text{O}=\text{C}_{10}\text{H}_{14}$	-47.0 (d) -73.0 (quin)	127
$[\text{AsF}_6]^-$	-57.6 <sup>c</sup>	--
$\text{C}_{10}\text{H}_{14}\text{F}_2$	-98.58 (s) <sup>d</sup>	--

<sup>a</sup> Abbreviations: (s) singlet; (d) doublet; (quin) quintet; (ax) axial; (eq) equatorial; (sh) shoulder; (br) broad. Unidentified impurity at  $-17\text{ ppm}$ .

<sup>b</sup>  $^1\Delta^{19}\text{F}(^{34}/^{32}\text{S}) = 0.060\text{ ppm}$ . <sup>c</sup>  $^1J(^{19}\text{F}-^{75}\text{As})$  not resolved, quadrupolar collapsed.

<sup>d</sup>  $^1J(^{19}\text{F}-^{13}\text{C}) = 268\text{ Hz}$ .

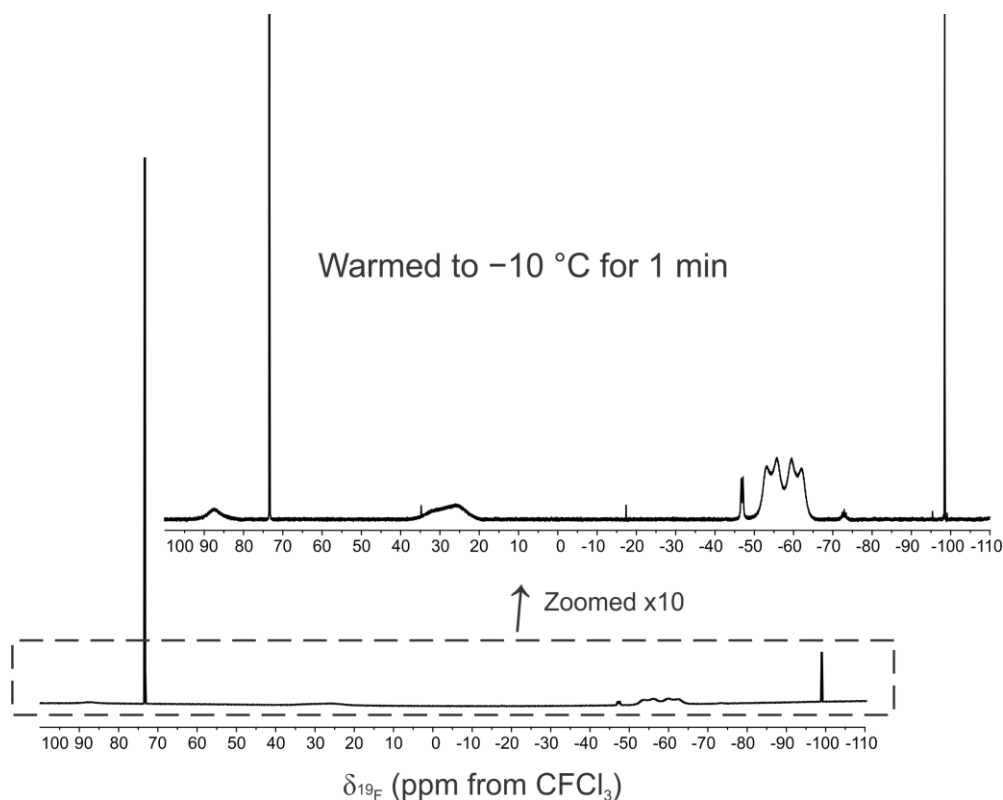

Figure 4.13  $^{19}\text{F}$  NMR spectrum (282.40 MHz) showing the reaction of  $[\text{SF}_3][\text{AsF}_6]$  with two molar equivalents of 2-adamantanone in  $\text{SO}_2$  at  $-40\text{ }^{\circ}\text{C}$ . The reaction was briefly warmed to  $-10\text{ }^{\circ}\text{C}$  to dissolve the product. Externally referenced to  $\text{CFCl}_3$  at RT.

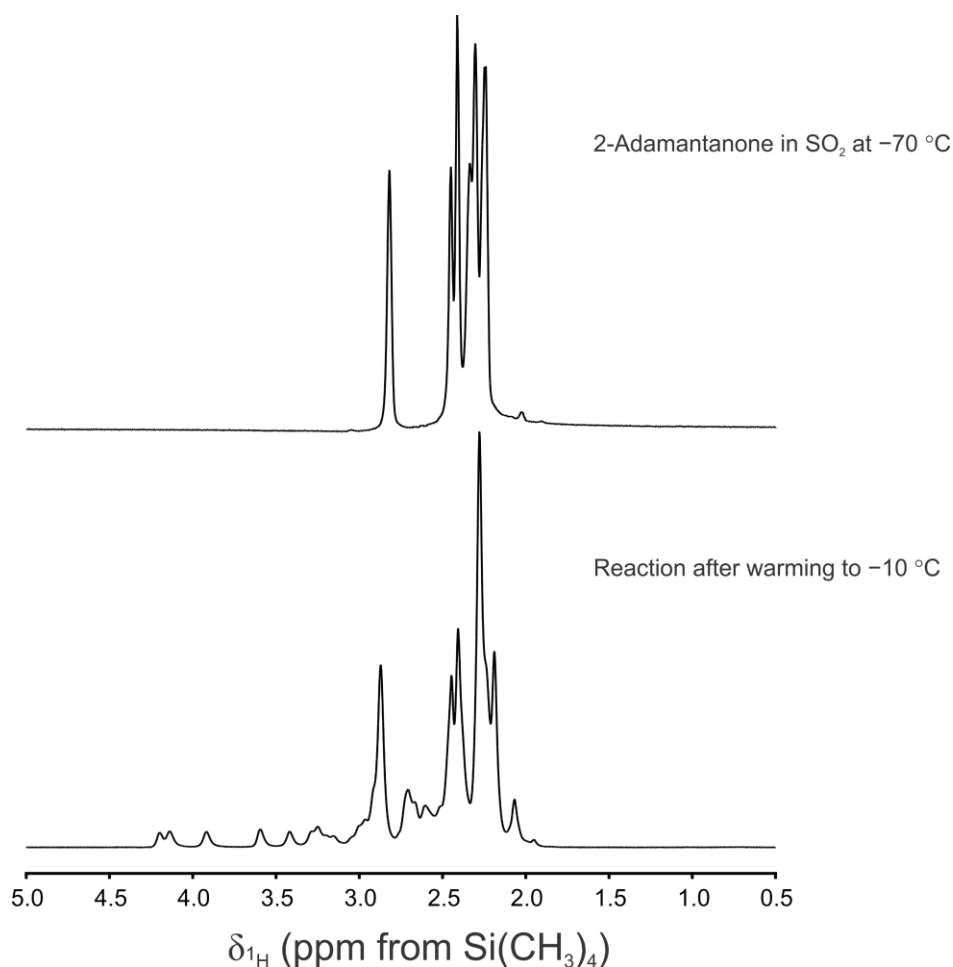

Figure 4.14  $^1\text{H}$  NMR spectra (300.13 MHz) showing the reaction of  $[\text{SF}_3][\text{AsF}_6]$  with 2 equivalents of 2-adamantanone in  $\text{SO}_2$  at  $-40\text{ }^\circ\text{C}$  after having been warmed to  $-10\text{ }^\circ\text{C}$  compared to 2-adamantanone in  $\text{SO}_2$  at  $-70\text{ }^\circ\text{C}$ . Externally referenced to  $\text{Si}(\text{CH}_3)_4$  at RT.

The doublet ( $-47.0\text{ ppm}$ ) and quintet ( $-73.0\text{ ppm}$ ) resonances (Figure 4.13) associated with the  $\text{AsF}_5\cdot\text{O}=\text{C}_{10}\text{H}_{14}$  adduct were also detected in the  $^{19}\text{F}$  NMR spectrum after warming to  $-10\text{ }^\circ\text{C}$ . Based on the reactions of  $[\text{SF}_3][\text{AsF}_6]$  with cyclopentanone and acetone, the use of two equivalents of Lewis base should result in only negligible concentrations of the  $\text{AsF}_5\cdot\text{O}=\text{R}$  adduct, however, using two equivalents of 2-adamantanone resulted in the formation of significant amounts of  $\text{AsF}_5\cdot\text{O}=\text{C}_{10}\text{H}_{14}$ .

The broad singlet at  $25.6\text{ ppm}$  was attributed to the  $[\text{SF}_3\cdot(\text{O}=\text{C}_{10}\text{H}_{14})_2]^+$  cation (Figure 4.13) and the  $[\text{AsF}_6]^-$  anion was observed at  $-57.6\text{ ppm}$  as a partially quadrupolar

collapsed multiplet suggesting some cation-anion interactions. The deoxofluorination products 2,2-difluoroadamantane (−98.58 ppm) and SOF<sub>2</sub> (73.32 ppm) were detected with an integration ratio of 0.3:1.0.

#### 4.2.9 [SF<sub>3</sub>][AsF<sub>6</sub>] and One Equivalent of 2-Adamantanone in SO<sub>2</sub>

Unlike the reaction of [SF<sub>3</sub>][AsF<sub>6</sub>] with two equivalents of 2-adamantanone in SO<sub>2</sub>, the use of a 1:1 molar ratio did not produce any solubility challenges at −70 °C and resulted in a clear colourless solution upon reaction. All reaction products were characterized at −70 °C in SO<sub>2</sub> using <sup>19</sup>F NMR spectroscopy. While <sup>1</sup>H NMR spectra were acquired, the spectra proved to be quite complex and did not provide any additional information in determining the products of this reaction. The <sup>19</sup>F NMR spectra are depicted in Figure 4.15 and the chemical shifts and coupling constants are listed in Table 4.11.

Upon melting at −70 °C, a broad singlet resonance at 31 ppm was observed associated with the [SF<sub>3</sub>·O=C<sub>10</sub>H<sub>14</sub>]<sup>+</sup> adduct, as well as, a broad quadrupolar collapsed singlet at −57 ppm associated with the [AsF<sub>6</sub>]<sup>−</sup> anion. Immediately upon warming the reaction, the [SF<sub>3</sub>·O=C<sub>10</sub>H<sub>14</sub>]<sup>+</sup> adduct began to dissociate into free SF<sub>4</sub> and AsF<sub>5</sub>·O=C<sub>10</sub>H<sub>14</sub> (Equation 4.5) as demonstrated by the appearance of a doublet at −46.6 ppm and a quintet at −71.4 ppm. This adduct increased in concentration upon warming to −40 °C, which resulted in a clear, light yellow solution. This was accompanied by a shift in the broad [SF<sub>3</sub>]<sup>+</sup> resonance to 37 ppm due to the formation of SF<sub>4</sub> in solution which rapidly exchanges with [SF<sub>3</sub>]<sup>+</sup>, as seen for the acetone and cyclopentanone systems. Additional resonances at −94.60 and −98.82 ppm were detected as singlets; the resonance at −98.82 ppm is likely associated with the deoxofluorination of 2-adamantanone to 2,2-difluoroadamantane.<sup>[10]</sup>

Table 4.11 Selected  $^{19}\text{F}$  chemical shifts ( $\delta$ ) at  $-70\text{ }^{\circ}\text{C}$  for the reaction of  $[\text{SF}_3][\text{AsF}_6]$  with one molar equivalent of 2-adamantanone in  $\text{SO}_2$ .

Compound	Chemical Shift (ppm) <sup>a</sup>	$^2J(^{19}\text{F}-^{19}\text{F})$ (Hz)

<sup>c</sup>  $^1\Delta^{19}\text{F}(^{34/32}\text{S}) = 0.060$  ppm. <sup>d</sup>  $^1J(^{19}\text{F}-^{75}\text{As})$  not resolved, quadrupolar collapsed.

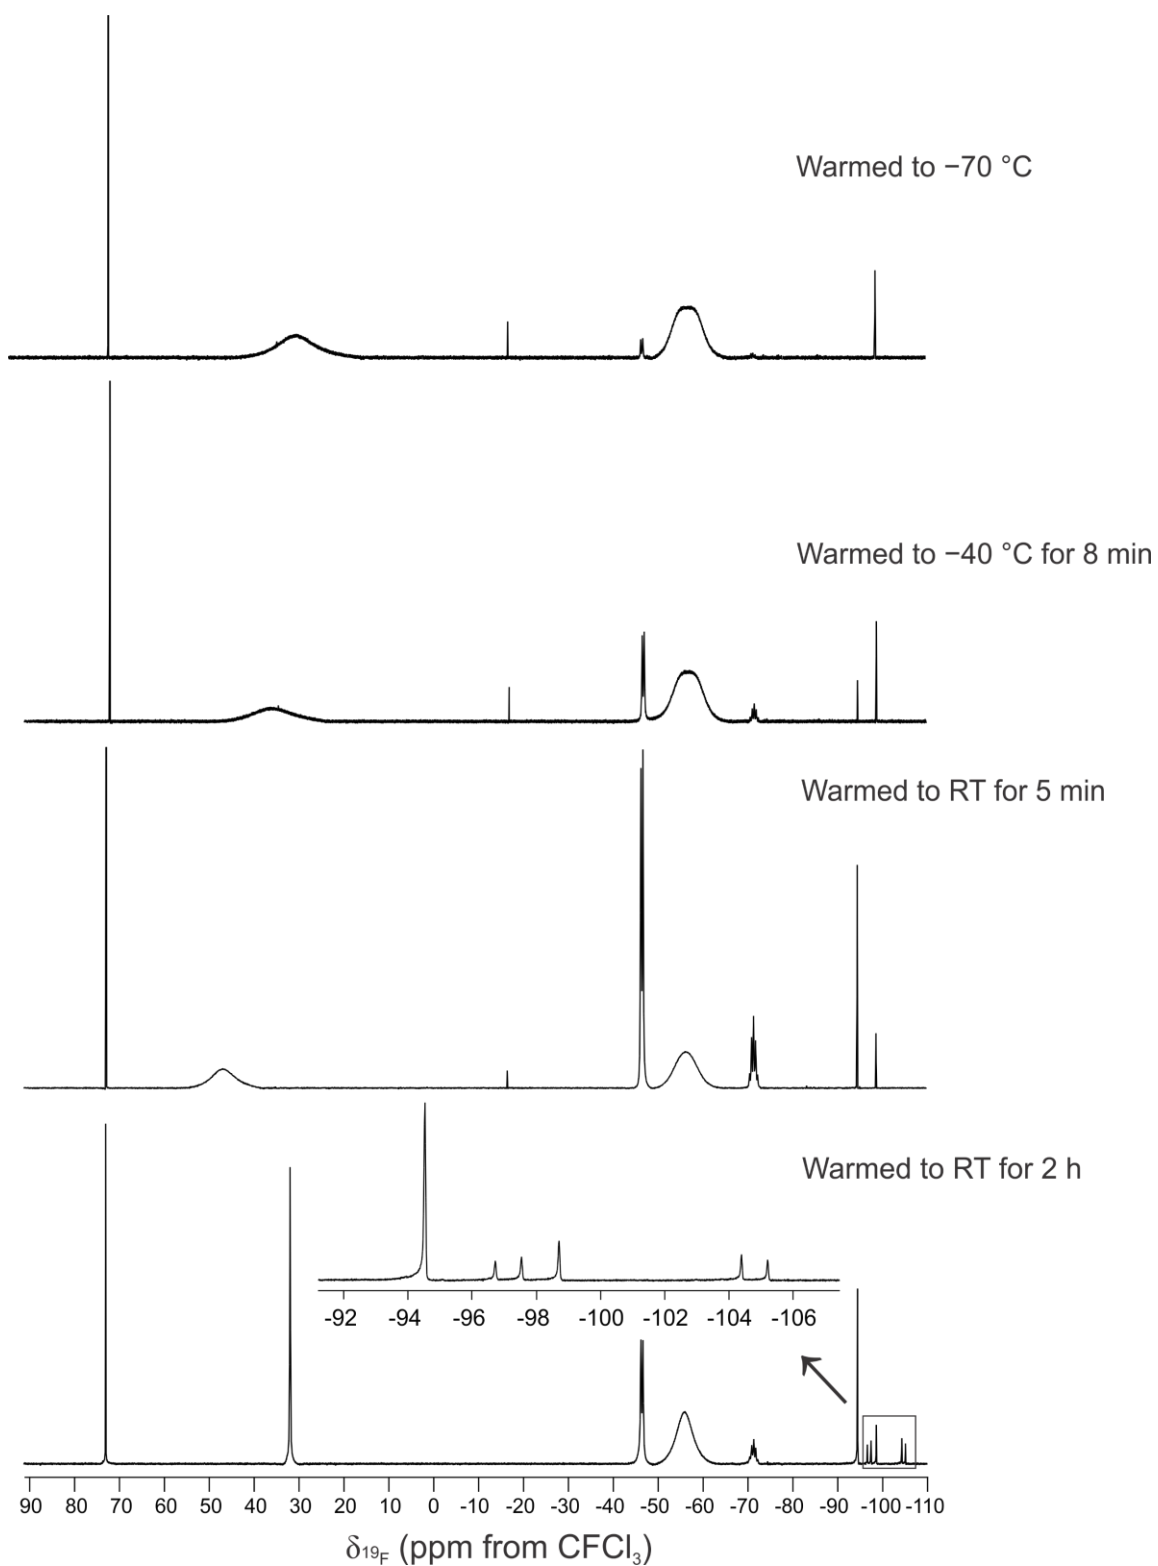

Figure 4.15  $^{19}\text{F}$  NMR spectra (282.40 MHz) showing the progress of the reaction of  $[\text{SF}_3][\text{AsF}_6]$  with 2-adamantanone in  $\text{SO}_2$  at  $-70^\circ\text{C}$  in a 1:1 molar ratio. All spectra were externally referenced to  $\text{CCl}_3$  at RT.

Warming the reaction to RT for 5 min resulted in a large increase in intensity of the  $\text{AsF}_5 \cdot \text{O}=\text{C}_{10}\text{H}_{14}$  resonances and an increase in the chemical shift of the  $[\text{SF}_3]^+/\text{SF}_4$  resonance (46 ppm), indicating the increased concentration of  $\text{SF}_4$ . The singlet at  $-94.62$  ppm increased in intensity, which may have resulted from fluorination of the adamantane ring by  $\text{SF}_4$ . The  $\text{AsF}_5 \cdot \text{O}=\text{C}_{10}\text{H}_{14}$  adduct remained relatively stable even after leaving the reaction at RT for 2 h, however, no  $\text{SF}_4$  remained and only a sharp singlet resonance at  $31.76$  ppm associated with free  $[\text{SF}_3]^+$  was present. The  $\text{SF}_4$  presumably reacted with the adamantane ring to yield more of the fluorinated adamantane product. When warmed to RT for 5 min the largest amount of  $\text{AsF}_5 \cdot \text{O}=\text{C}_{10}\text{H}_{14}$  adduct was generated, relative to the  $[\text{AsF}_6]^-$ ; for every one  $[\text{AsF}_6]^-$ , one equivalent of  $\text{AsF}_5 \cdot \text{O}=\text{C}_{10}\text{H}_{14}$  was formed as detected by the characteristic doublet ( $F_{\text{eq}}$ :  $-46.66$  ppm) and quintet ( $F_{\text{ax}}$ :  $-71.53$  ppm) resonances in the  $^{19}\text{F}$  NMR spectrum. The relative integrations after 2 h at RT were 3.0:12.0:3.5:1.0 for  $[\text{SF}_3]^+$ ,  $[\text{AsF}_6]^-$ , and the doublet ( $F_{\text{eq}}$ ) and quintet ( $F_{\text{ax}}$ ) resonances of  $\text{AsF}_5 \cdot \text{O}=\text{C}_{10}\text{H}_{14}$ , respectively. For every one  $\text{AsF}_5 \cdot \text{O}=\text{C}_{10}\text{H}_{14}$  present, two  $[\text{AsF}_6]^-$  anions exist and for every one  $\text{SOF}_2$  generated, 4 molar equivalents of the  $\text{AsF}_5 \cdot \text{O}=\text{C}_{10}\text{H}_{14}$  adduct are present (integration of 2.0:14.1:4.1 for  $\text{SOF}_2:\text{AsF}_5 \cdot \text{O}=\text{C}_{10}\text{H}_{14}$ ). The resonance attributed to 2,2-difluoroadamantane ( $-98.71$  ppm) decreased in intensity and an AB pattern centered around  $-97.14$  and  $-104.81$  ppm with a  $J = 230$  Hz was observed, which is common for geminal  $^2J(^{19}\text{F}-^{19}\text{F})$  coupling. This suggests that the adamantane ring was broken up as 2-fluoroadamantane ( $-173$  ppm), 1-fluoroadamantane ( $-128$  ppm), and 2-fluoroadamantane cation,  $[\text{C}_{10}\text{H}_{14}\text{F}]^+$  ( $120$  ppm), products were not observed.<sup>[10]</sup> Generating approximately 4 equivalents of  $\text{SOF}_2$  yielded 1 equivalent of 2,2-difluoroadamantane, approximately two equivalents of the unknown difluoro-species at  $-97.14$  and  $-104.81$  ppm, and

approximately 5 equivalents of the unidentified species at  $-94.54$  ppm (relative integration of 7.5:9.6:2.5:2.0:2.4).

#### 4.2.10 Computational Studies of Possible Deoxofluorination Intermediates

Density functional theory (DFT) calculations were carried out on the following five proposed potential intermediates of the deoxofluorination reaction of acetone:  $[\text{SF}_3 \cdot \text{O}=\text{C}(\text{CH}_3)_2]^+$ ,  $[\text{SF}_3 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_2]^+$ ,  $[\text{SF}_3 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_3]^+$ ,  $(\text{CH}_3)_2\text{FCOSF}_3$ , and  $[(\text{CH}_3)_2\text{FCOSF}_2]^+$ . The gas-phase geometries of these compounds were optimized using the B3LYP/aug-cc-pVTZ level of theory and are shown in Figure 4.16. A summary of selected geometric parameters is given in Table 4.12.

Table 4.12 Selected Calculated Bond Lengths (Å) of  $[\text{SF}_3 \cdot \text{O}=\text{C}(\text{CH}_3)_2]^+$ ,  $[\text{SF}_3 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_2]^+$ ,  $[\text{SF}_3 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_3]^+$ ,  $(\text{CH}_3)_2\text{FCOSF}_3$ , and  $[(\text{CH}_3)_2\text{FCOSF}_2]^+$ .

Compound	S–O	C–O	S–F	C–F

$[(\text{CH}_3)_2\text{FCOSF}_2]^+$	1.451	C(2)–O(1) 2.542	S(1)–F(1) 1.600 S(1)–F(2) 1.602	1.279

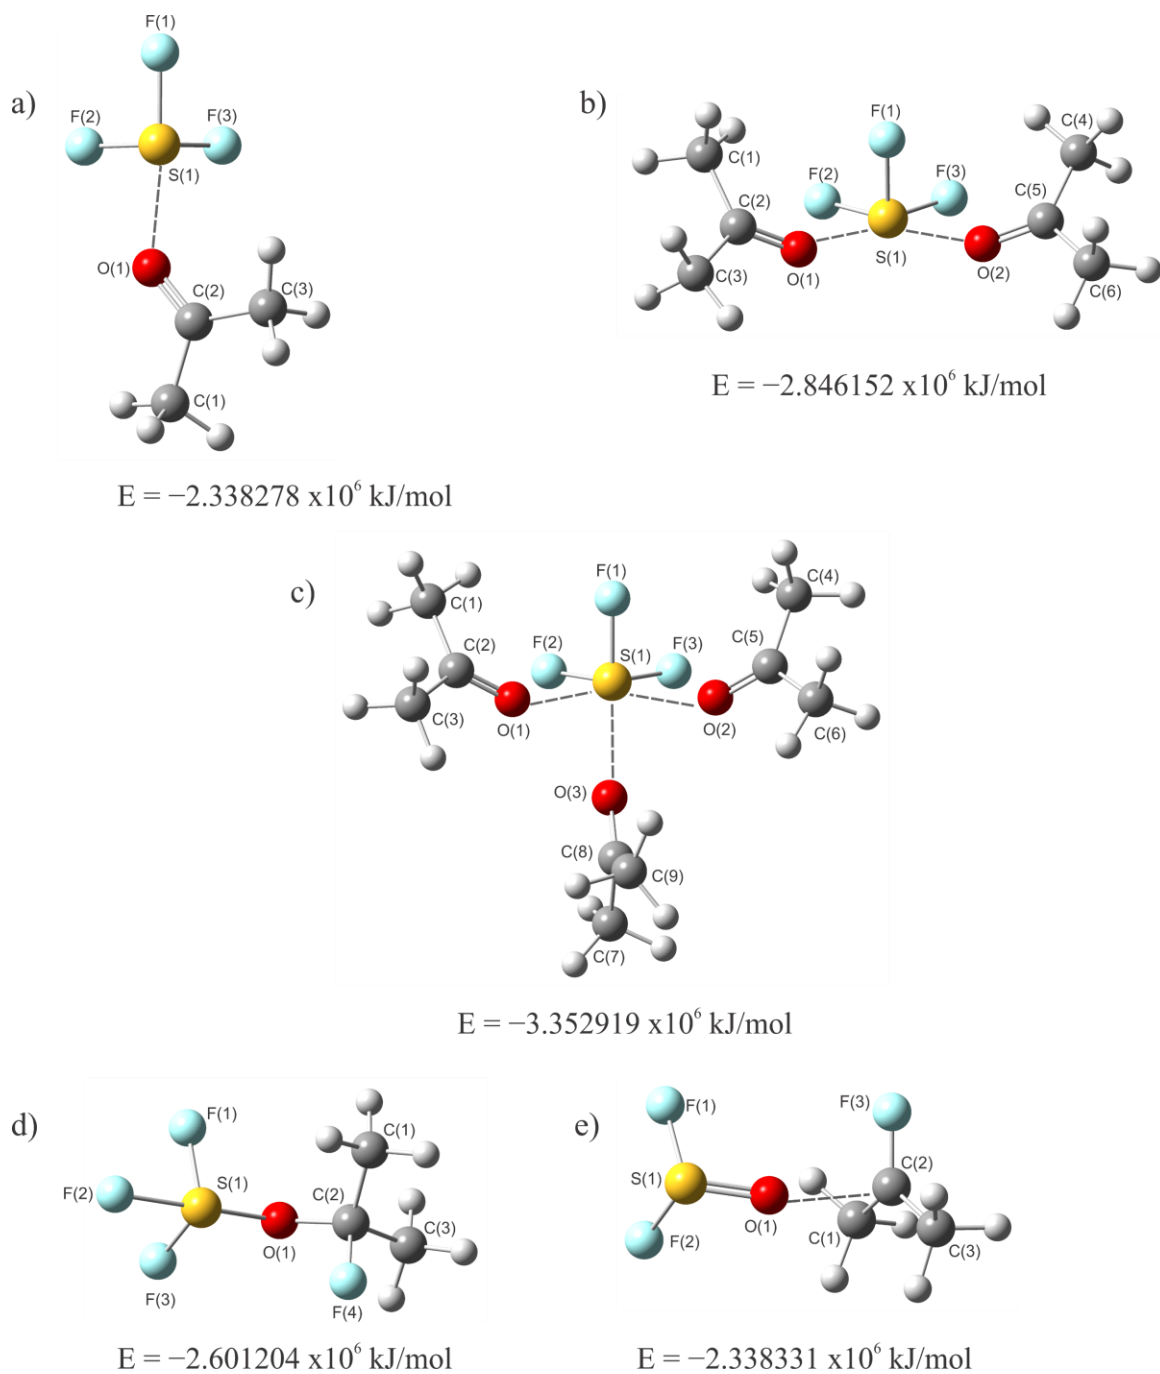

Figure 4.16 Optimized gas-phase geometries and energies of possible intermediates in the deoxofluorination reaction: a)  $[\text{SF}_3 \cdot \text{O}=\text{C}(\text{CH}_3)_2]^+$ , b)  $[\text{SF}_3 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_2]^+$ , c)  $[\text{SF}_3 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_3]^+$ , d)  $(\text{CH}_3)_2\text{FCOSF}_3$ , and e)  $[(\text{CH}_3)_2\text{FCOSF}_2]^+$ .

It was first suggested by Dmowski that the  $[\text{SF}_3 \cdot \text{O}=\text{C}(\text{CH}_3)_2]^+$  cation is the first intermediate in the deoxofluorination reaction mechanism and responsible for polarizing the C=O bond of acetone (see Chapter 1 for more details). The NMR spectroscopy studies described in Section 4.2.2–4.2.5 showed the ability of  $[\text{SF}_3]^+$  to form adducts with acetone when reacted in 1:1, 1:2 and 1:3 ratios in  $\text{SO}_2$  at low-temperatures ( $< -40^\circ\text{C}$ ). In the case where excess acetone was reacted with  $[\text{SF}_3]^+$ , the  $[\text{SF}_3 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_3]^+$  cation was proposed to exist, which did not form in the case where three equivalents of acetone were used. The calculated S–O bond lengths of the  $[\text{SF}_3 \cdot \text{O}=\text{C}(\text{CH}_3)_2]^+$  (2.157 Å),  $[\text{SF}_3 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_2]^+$  (2.299 and 2.300 Å), and  $[\text{SF}_3 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_3]^+$  (2.359–2.504 Å) cations increase as more acetone molecules are added to the coordination sphere of the sulfur in  $[\text{SF}_3]^+$ . Consequently, the  $[\text{SF}_3]^+$  cation will not polarize the C=O bond to as large of an extent resulting in shorter C=O bond lengths as more acetones are added (C–O bond lengths: acetone 1.210 Å;  $[\text{SF}_3 \cdot \text{O}=\text{C}(\text{CH}_3)_2]^+$  1.242 Å;  $[\text{SF}_3 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_2]^+$  1.233 Å; and  $[\text{SF}_3 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_3]^+$  1.226–1.229 Å). In the  $[\text{SF}_3 \cdot \text{O}=\text{C}(\text{CH}_3)_2]^+$  cation, the acetone coordinates to the sulfur via the axial position (F(1)–S(1)–O(1)  $173.3^\circ$ ) and the lone pair on sulfur occupies the equatorial position of the trigonal bipyramidal geometry. The  $[\text{SF}_3 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_2]^+$  cation adopts a square pyramidal geometry with the two acetone molecules coordinating to the sulfur in the equatorial positions (F(3)–S(1)–O(1)  $179.40^\circ$ ; F(2)–S(1)–O(2)  $179.62^\circ$ ). Lastly, the gas-phase geometry of  $[\text{SF}_3 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_3]^+$  is octahedral with three equatorial acetone ligands coordinating trans to a S–F bond (F(3)–S(1)–O(1)  $178.33^\circ$ ; F(2)–S(1)–O(2)  $178.59^\circ$ ; F(1)–S(1)–O(3)  $170.93^\circ$ ).

Based on the deoxofluorination reaction mechanism proposed by Pustovit and Nazaretian, the  $[\text{SF}_3 \cdot \text{O}=\text{C}(\text{CH}_3)_2]^+$  cation undergoes nucleophilic attack at the carbon center by a fluoride source to generate the neutral  $(\text{CH}_3)_2\text{FCOSF}_3$ . The optimized gas-phase

geometry of this species was calculated, along with the  $[(\text{CH}_3)_2\text{FCOSF}_2]^+$  cation which is proposed to be in equilibrium with  $(\text{CH}_3)_2\text{FCOSF}_3$  in the presence of HF. The  $(\text{CH}_3)_2\text{FCOSF}_3$  compound contained S–O (1.726 Å) and C–O (1.413 Å) single bonds and the C(2) center adopted a tetrahedral geometry (O(1)–C(2)–F(4) 107.52°). The  $[(\text{CH}_3)_2\text{FCOSF}_2]^+$  cation optimized to  $\text{SOF}_2$  and  $[(\text{CH}_3)_2\text{CF}]^+$  with a weak O(1)–C(2) interaction of 2.542 Å ( $\sum r_{\text{vdW}} = 3.22$  Å). The optimized structure showed the  $[(\text{CH}_3)_2\text{CF}]^+$  moiety to be nearly planar with a sum of angles about the central carbon of 359.36° deviating only slightly from 360° for a trigonal planar geometry. This strongly supports the proposed mechanism by Pustovit and Nazaretian, which states that  $[(\text{CH}_3)_2\text{FCOSF}_2]^+$  readily loses  $\text{SOF}_2$  and allows for nucleophilic attack by a fluoride source (i.e.,  $[\text{HF}_2]^-$ ) yielding 2,2-difluoropropane.

The HOMO and LUMO energies of the  $[\text{SF}_3 \cdot \text{O}=\text{C}(\text{CH}_3)_2]^+$ ,  $[\text{SF}_3 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_2]^+$ , and  $[\text{SF}_3 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_3]^+$  cations were calculated and are listed in Table 4.13. The LUMO energies decreased as more acetone molecules were added around  $[\text{SF}_3]^+$  ( $[\text{SF}_3 \cdot \text{O}=\text{C}(\text{CH}_3)_2]^+ -732$  kJ/mol;  $[\text{SF}_3 \cdot (\text{O}=\text{C}(\text{CH}_3)_2)_2]^+ -613$  kJ/mol; and  $[\text{SF}_3 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_3]^+ -500$  kJ/mol) compared to neutral acetone (–18 kJ/mol). The  $[\text{SF}_3]^+$  cation is highly Lewis acidic and reacts readily with ketones, as shown by NMR spectroscopy and the observed colour changes of the reactions, even at low temperatures (*vide supra*). The low energy of the LUMO makes the carbon of the carbonyl group much more readily available towards nucleophilic attack. These values can be compared to the calculated LUMO energies of the oxonium cations  $[\text{HO}=\text{C}(\text{CH}_3)_2]^+$  (–189 kJ/mol) and  $[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_2]^+$  (–596 kJ/mol) (presented in Chapter 5) which are much more thermally stable even at RT, in the case of  $[\text{HO}=\text{C}(\text{CH}_3)_2]^+$ .

Table 4.13 Calculated Energies (kJ/mol) of the HOMO and LUMO for  $[\text{SF}_3 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_x]^+$  ( $x = 1-3$ ) and Protonated Ketones  $[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_x]^+$  ( $x = 1, 2$ ).

Compound	HOMO Energy	LUMO Energy
$\text{O}=\text{C}(\text{CH}_3)_2$	-162	-18
$[\text{HO}=\text{C}(\text{CH}_3)_2]^+$	-376	-189
$[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_2]^+$	-1203	-596
$[\text{SF}_3 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_3]^+$	-1035	-500
$[\text{SF}_3 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_2]^+$	-1126	-613
$[\text{SF}_3 \cdot \text{O}=\text{C}(\text{CH}_3)_2]^+$	-1271	-732

### 4.3 Summary and Conclusions

A detailed study of the reactions between  $[\text{SF}_3][\text{AsF}_6]$  and the ketones, acetone, cyclopentanone, and 2-adamantanone, has been carried out using  $^{19}\text{F}$  and  $^1\text{H}$  NMR spectroscopy at low temperatures. The 1:1 and 1:2 adducts of  $[\text{SF}_3]^+$  with the ketones, acetone, cyclopentanone, and 2-adamantanone, have been observed at low temperatures in  $\text{SO}_2$  for the first time by NMR spectroscopy. The reaction of  $[\text{SF}_3][\text{AsF}_6]$  with an excess of acetone (i.e., as the solvent) at  $-80^\circ\text{C}$  resulted in a decrease in the  $\delta(^{19}\text{F})$  from 32.91 to 18.43 ppm attributed to the formation of the 1:3 adduct,  $[\text{SF}_3 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_3]^+$ . DFT calculations were used to optimize the gas-phase geometry of these adducts and structural parameters were reported. As well, the geometries of the proposed intermediates of deoxofluorination,  $(\text{CH}_3)_2\text{FCOSF}_3$  and  $[(\text{CH}_3)_2\text{FCOSF}_2]^+$ , were optimized in the gas phase. For each of the reactions performed, gradually warming to  $-40^\circ\text{C}$  resulted in a colour change to a dark red or orange/brown and the appearance of  $\text{SF}_4$  in the  $^{19}\text{F}$  NMR spectrum. This was attributed to the presumed dismutation reaction of two equivalents of  $[\text{SF}_3][\text{AsF}_6]$  to  $\text{SF}_4$  and  $[\text{SF}_2 \cdot (\text{O}=\text{R})_x][\text{AsF}_6]$  ( $\text{R} = \text{C}(\text{CH}_3)_2, \text{C}_5\text{H}_8, \text{C}_{10}\text{H}_{14}; x = 1-3$ ). The proposed  $[\text{SF}_2]^{2+}$

product has not been observed and is likely too oxidatively reactive to be stabilized in these solutions.

The reactions between  $[\text{SF}_3][\text{AsF}_6]$  and ketone in a 1:1 ratio consistently gave the  $\text{AsF}_5 \cdot \text{O}=\text{R}$  adduct ( $\text{R} = \text{C}(\text{CH}_3)_2$ ,  $\text{C}_5\text{H}_8$ ,  $\text{C}_{10}\text{H}_{14}$ ) as a by-product. This was likely due to the strong  $\text{F}_3\text{S} \cdots \text{FAsF}_5$  interactions and insufficient concentration of the carbonyl compound to shield  $[\text{SF}_3]^+$  from interacting with the anion. The reaction with 2-adamantanone, when warmed to RT for 5 min, gave the largest amount of  $\text{AsF}_5 \cdot \text{O}=\text{C}_{10}\text{H}_{14}$  adduct relative to the  $[\text{AsF}_6]^-$  anion as detected by the characteristic doublet ( $F_{\text{eq}}$ :  $-46.66$  ppm) and quintet ( $F_{\text{ax}}$ :  $-71.53$  ppm) resonances in the  $^{19}\text{F}$  NMR spectrum.

Despite the lack of  $\text{F}^-$  present, required for conversion of a  $\text{C}=\text{O}$  group to a  $-\text{CF}_2$  group, some reactions yielded the deoxofluorination product (i.e., the difluoro species) in very small amounts. Upon warming these reactions to RT, dark coloured solutions were generated, attributed to the existence of a radical cation, which could not be detected via NMR spectroscopy. The radical cation was possibly generated from the reaction of the ketone with the highly reactive and elusive  $[\text{SF}_2]^{2+}$  species.

## 5. Solid-State Structure of Protonated Ketones and Aldehydes in Superacidic Media

(Based on publication: Stuart, D.; Wetmore, S. D.; Gerken, M. *Angew. Chem. Int. Ed.* **2017**, 56, 16380–16384)

### 5.1 Introduction

Protonated ketones and aldehydes are key intermediates in many organic reactions. Ground-breaking work by Gillespie and Olah proved by NMR spectroscopy that these cationic intermediates can be stabilized in superacidic solutions at low temperatures (LT).<sup>[1]</sup> Olah studied the protonation of a suite of organic molecules with varying functional groups including ketones, aldehydes, alcohols, ethers, thiols, and carboxylic acids.<sup>[1a]</sup> The use of superacidic media, such as  $\text{HSO}_3\text{F-SbF}_5$  (“magic acid”) or  $\text{HF/SbF}_5$ , provide proton sources for the organic intermediates and stabilize these protonated compounds. One of the first ketones to be studied by  $^1\text{H}$  NMR spectroscopy was the conjugate acid of acetone, with a  $\text{pK}_\text{a}$  of  $-7.3$ , giving rise to a  $^1\text{H}$  resonance of the  $\text{C=OH}^+$  group at 14.45 ppm.<sup>[1b]</sup> Two resonance structures can be written for protonated ketones and aldehydes: the oxonium and hydroxycarbenium cation structures (Scheme 5.1). Strong evidence for the oxonium structure being favoured has been obtained by the highly deshielded  $^1\text{H}$  resonances between 13 and 15 ppm,<sup>[1c-e]</sup> as well as by the observation of the *E*- and *Z*-stereoisomers of protonated aldehydes and unsymmetrically substituted ketones.<sup>[1d,e]</sup>

Scheme 5.1 Resonance structures for protonated ketones.

A small number of protonated ketones have been studied in the solid state. Structural studies of monoprotonated ketones are limited to a group of cyclopropylcarbinyl derivatives which were part of investigations of the stabilization of a positive charge by cyclopropyl groups and in homoaromatic systems (Figure 5.1).<sup>[2]</sup> In one attempt to isolate the 2-hydroxyhomotropylium benzannelated cation, the X-ray crystal structure showcased a hemiprotonated cation consisting of two hydrogen-bridged ketones.<sup>[3]</sup>

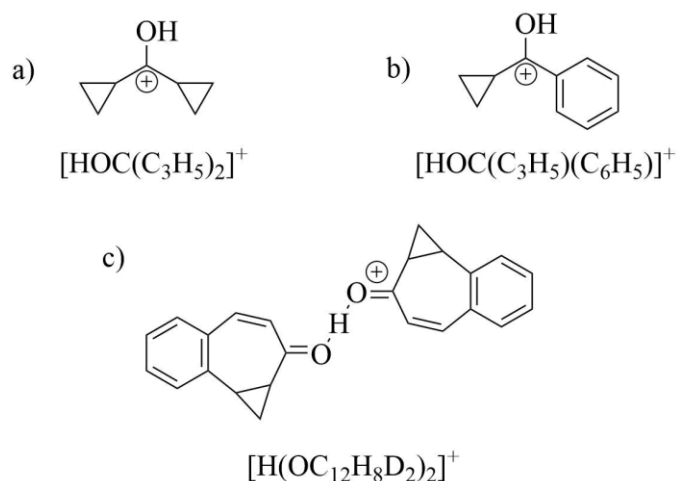

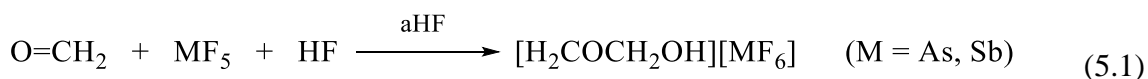

Figure 5.1 Structures of the previous protonated cyclopropylcarbinyl derivatives studied.

In a study involving the isolation of solvated protons in organic oxygen-donor solvents, the X-ray crystal structure of hemiprotonated benzophenone was determined.<sup>[4]</sup> Computational studies using the B3LYP/6-31++G(d,p) level of theory have been carried out on the carbonyl bases  $\text{R}_2\text{C}=\text{O}$  ( $\text{R} = \text{F}, \text{H}, \text{CH}_3$ ), investigating the changes in bond lengths and vibrational frequencies upon protonation.<sup>[5]</sup> It was predicted that a dramatic decrease of up to  $232 \text{ cm}^{-1}$  in the  $\nu(\text{CO})$  stretching frequency and increase in the  $\text{C}=\text{O}$  bond distances occurred once the carbonyl group was protonated. Semi-empirical studies in conjunction with mass spectrometric measurements have been used to study the geometric properties and stability of protonated acetone clusters.<sup>[6]</sup>

Currently, no solid-state studies of protonated aldehydes have been reported. Infrared photodissociation spectroscopy along with calculations at the B3LYP/6-311++G(2df,2pd) level of theory were used to probe protonated benzaldehyde.<sup>[7]</sup> Excited state and optimized geometry calculations showed the lowest-energy configuration to be the *E*-configuration.<sup>[8]</sup> Mass spectrometry studies, along with gas-phase calculations, have suggested that formaldehyde and acetaldehyde form hydrogen-bridged dimers, (RCHO)<sub>2</sub>H<sup>+</sup> (R = H or CH<sub>3</sub>).<sup>[9]</sup> Attempts to synthesize protonated formaldehyde in the solid state have been unsuccessful and instead a [H<sub>2</sub>C=O-CH<sub>2</sub>OH]<sup>+</sup> salt was obtained and characterized by X-ray crystallography and IR and Raman spectroscopies (Equation 5.1).<sup>[10]</sup>

## 5.2 Results and Discussion

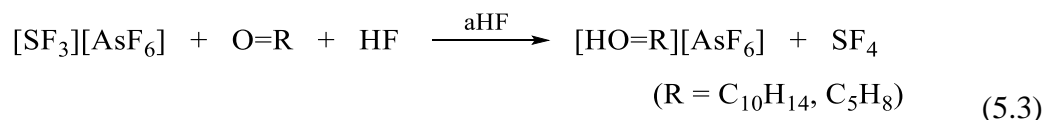

### 5.2.1 Synthesis and Properties of Protonated 2-Adamantanone, Cyclopentanone, Acetone, Benzaldehyde, and Acetaldehyde

While investigating the reaction mechanism of deoxofluorination reactions between ketones and the highly Lewis acidic [SF<sub>3</sub>]<sup>+</sup> cation, an equimolar reaction between the [SF<sub>3</sub>][AsF<sub>6</sub>] salt and 2-adamantanone (O=C<sub>10</sub>H<sub>14</sub>) in anhydrous hydrogen fluoride (aHF) resulted in protonation of the carbonyl group and the synthesis of the [AsF<sub>6</sub>]<sup>−</sup> salt of [HO=C<sub>10</sub>H<sub>14</sub>]<sup>+</sup>. The protonation of the ketone can be explained by the superacidic nature of the [SF<sub>3</sub>][AsF<sub>6</sub>]/aHF system (Equation 5.2). In excess aHF, formation of SF<sub>4</sub> and [H<sub>2</sub>F][AsF<sub>6</sub>], a proton source, were formed in solution. Upon isolating the product, the SF<sub>4</sub> produced was easily removed under dynamic vacuum.

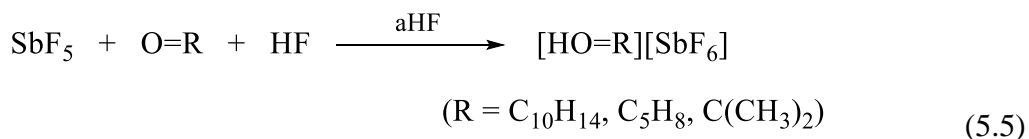

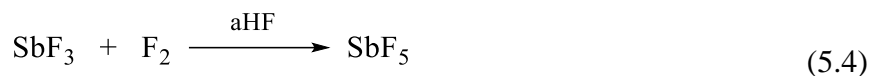

In targeted reactions, salts of the protonated ketones, [2-adamantanone ( $\text{O}=\text{C}_{10}\text{H}_{14}$ ), cyclopentanone ( $\text{O}=\text{C}_5\text{H}_8$ ), acetone ( $\text{O}=\text{C}(\text{CH}_3)_2$ )] and protonated aldehydes, [benzaldehyde ( $\text{O}=\text{CHC}_6\text{H}_5$ ), acetaldehyde ( $\text{O}=\text{CHCH}_3$ )] were isolated using stoichiometric amounts of either  $[\text{SF}_3][\text{AsF}_6]$  or  $\text{SbF}_5$  in aHF. Reactions using  $\text{AsF}_5$  were attempted, but led to inaccurate stoichiometric ratios, which resulted in reduced stability of the product, likely due to oxidation of the organic substrate by excess  $\text{AsF}_5$ .

Reactions of  $[\text{SF}_3][\text{AsF}_6]$  with  $\text{O}=\text{C}_{10}\text{H}_{14}$  and  $\text{O}=\text{C}_5\text{H}_8$  in aHF at  $-78^\circ\text{C}$  yielded the hexafluoroarsenate salts of  $[\text{HO}=\text{C}_{10}\text{H}_{14}]^+$  and  $[\text{HO}=\text{C}_5\text{H}_8]^+$ , respectively (Equation 5.3). Reaction occurred instantaneously upon melting, producing white powders that dissolved at  $0^\circ\text{C}$ . Crystals of  $[\text{HO}=\text{C}_{10}\text{H}_{14}][\text{AsF}_6]$  and  $[\text{HO}=\text{C}_5\text{H}_8][\text{AsF}_6]$  were grown at  $-20$  and  $-78^\circ\text{C}$ , respectively. The salt of  $[\text{HO}=\text{C}_{10}\text{H}_{14}]^+$  was stable at room-temperature (RT) for 20 min before turning pale yellow, whereas  $[\text{HO}=\text{C}_5\text{H}_8][\text{AsF}_6]$  was more stable and remained a white powder for upwards of 1 h. The bands in the LT Raman spectra showed no change in frequency; however, increasing fluorescence was observed in the spectral baseline the longer the sample was left at RT.

Hexafluoroantimonate salts can be obtained via the reaction of ketones with one molar equivalent of  $\text{SbF}_5$  in aHF. Stoichiometric amounts of  $\text{SbF}_5$  can be prepared from the reaction of a known amount of solid  $\text{SbF}_3$  with elemental fluorine in aHF (Equation 5.4). Subsequent addition of equimolar quantities of 2-adamantanone, cyclopentanone, and acetone resulted in immediate reactions at  $-78^\circ\text{C}$  producing white powders of

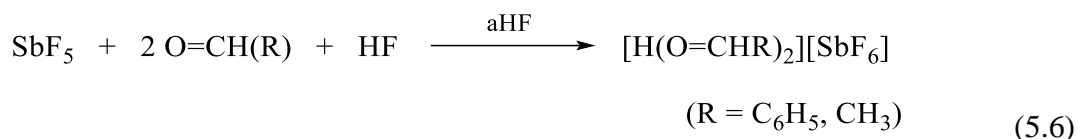

$[\text{HO}=\text{C}_{10}\text{H}_{14}][\text{SbF}_6]$ ,  $[\text{HO}=\text{C}_5\text{H}_8][\text{SbF}_6]$ , and  $[\text{HO}=\text{C}(\text{CH}_3)_2][\text{SbF}_6]$ , respectively, according to reaction equation 5.5. The  $[\text{HO}=\text{C}(\text{CH}_3)_2][\text{SbF}_6]$  salt proved to be the most stable among those studied, lasting 24 h at RT before LT Raman spectroscopy showed some fluorescence in the baseline.

By reacting two equivalents of acetone with  $\text{SbF}_5$  in aHF at  $-78^\circ\text{C}$ , it was believed the  $[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_2][\text{SbF}_6]$  salt could be synthesized. This reaction produced a white solid which was then dissolved by quickly bringing the sample to RT so that the solid dissolved. Clear, colourless blocks crystallized at  $-60^\circ\text{C}$  over a period of ca. 30 min. Instead of pure  $[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_2][\text{SbF}_6]$ , X-ray crystallography showed several of these crystals to be  $[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_2]_3[\text{HO}=\text{C}(\text{CH}_3)_2]_3[\text{SbF}_6]_5\text{F}$ , likely due to the actual stoichiometry being slightly less than 1:2. Several crystals were mounted and shown to have the same unit cell, however, the structure of the bulk sample was not determined. The stability of this salt was not tested.

The reaction of benzaldehyde ( $\text{O}=\text{CHC}_6\text{H}_5$ ) with  $\text{SbF}_5$  in aHF yielded the  $[\text{SbF}_6]^-$  salt of hemiprotonated, hydrogen-bridged dimeric  $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2]^+$ , even when a one molar equivalent of  $\text{SbF}_5$  was used (Equation 5.6). The sample was warmed to  $-60^\circ\text{C}$  to dissolve the solid, and pale red, transparent blocks crystallized at  $-78^\circ\text{C}$ . No evidence for the monoprotonated  $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2]^+$  cation was obtained by Raman spectroscopy or X-ray crystallography. Reacting acetaldehyde ( $\text{O}=\text{CHCH}_3$ ) with  $\text{SbF}_5$  in 2:1 and 1:1 molar

ratios, resulted in the synthesis of the  $[\text{SbF}_6]^-$  salts of  $[\text{H}(\text{O}=\text{CHCH}_3)_2]^+$  and  $[\text{HO}=\text{CHCH}_3]^+$ , respectively (Equation 5.6 and 5.7). The three salts,  $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2][\text{SbF}_6]$ ,  $[\text{H}(\text{O}=\text{CHCH}_3)_2][\text{SbF}_6]$ , and  $[\text{HO}=\text{CHCH}_3][\text{SbF}_6]$ , were isolated as white powders and characterized by Raman spectroscopy at low temperature proving to be unstable, decomposing upon warming to RT. The  $[\text{H}(\text{O}=\text{CHCH}_3)_2][\text{SbF}_6]$  salt was only obtained in admixture with  $[\text{HO}=\text{CHCH}_3][\text{SbF}_6]$ . The white powder produced easily dissolved at  $-70\text{ }^\circ\text{C}$  and colourless needles crystallized at  $-78\text{ }^\circ\text{C}$ . No single crystals suitable for X-ray crystallography were found.

### 5.2.2 X-ray Crystallography of Protonated Ketones

The crystallographic parameters and details for the protonated ketone salts  $[\text{HO}=\text{C}_{10}\text{H}_{14}][\text{AsF}_6]$ ,  $[\text{HO}=\text{C}_5\text{H}_8][\text{AsF}_6]$ ,  $[\text{HO}=\text{C}_5\text{H}_8][\text{SbF}_6]$ ,  $[\text{HO}=\text{C}(\text{CH}_3)_2][\text{SbF}_6]$ , and  $[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_2]_3[\text{HO}=\text{C}(\text{CH}_3)_2]_3[\text{SbF}_6]_5\text{F}$  are provided in Table 5.1. A summary of selected experimental and calculated bond lengths are listed in Table 5.2. A full list of experimental and calculated bond lengths and bond angles of the protonated ketones can be found in Appendix Tables A.2.1–A.2.6.

[a] Refers to the carbon *cis* or *trans* to the proton on the oxygen. [b] from Ref. 11; [c] from Ref. 12; [d] from Ref. 13; [e] DFT calculations at the B3LYP/aug-cc-pVTZ level of theory.

Crystals of [HO=C<sub>10</sub>H<sub>14</sub>][AsF<sub>6</sub>], [HO=C<sub>5</sub>H<sub>8</sub>][AsF<sub>6</sub>], [HO=C<sub>5</sub>H<sub>8</sub>][SbF<sub>6</sub>], and [HO=C(CH<sub>3</sub>)<sub>2</sub>][SbF<sub>6</sub>] were grown from aHF. The crystal structures of these salts (Figures 5.2–5.4) clearly show the protonation of 2-adamantanone, cyclopentanone, and acetone. As a result of protonation of the carbonyl group, the X-ray crystal structures show an increase in the C=O bond lengths ([HO=C<sub>10</sub>H<sub>14</sub>]<sup>+</sup> 1.274(2) Å; [HO=C<sub>5</sub>H<sub>8</sub>]<sup>+</sup> 1.266(3);

[HO=C(CH<sub>3</sub>)<sub>2</sub>]<sup>+</sup> 1.271(3) and 1.273(3) Å) compared to their respective parent ketones (O=C<sub>10</sub>H<sub>14</sub> 1.215(3) Å;<sup>[10]</sup> O=C<sub>5</sub>H<sub>8</sub> 1.21909(15) Å;<sup>[11]</sup> O=C(CH<sub>3</sub>)<sub>2</sub> 1.208(3) Å<sup>[12]</sup>) (Table 5.2). The C=O bond lengths of the protonated compounds, however, remain significantly shorter than the typical C–O single bond in an alcohol (1.432(13) Å).<sup>[13]</sup> As confirmed by DFT calculations at the B3LYP/aug-cc-pVTZ level of theory (Table 5.2), a significant decrease in the C<sub>C=O</sub>–C bond lengths is observed for the protonated ketones (C<sub>C=O</sub>–C<sub>cis</sub>: [HO=C<sub>10</sub>H<sub>14</sub>]<sup>+</sup> 1.469(2) Å; [HO=C<sub>5</sub>H<sub>8</sub>]<sup>+</sup> 1.473(3) Å; [HO=C(CH<sub>3</sub>)<sub>2</sub>]<sup>+</sup> 1.467(3) Å) relative to the parent compounds (O=C<sub>10</sub>H<sub>14</sub> 1.5176(16) Å;<sup>[10]</sup> O=C<sub>5</sub>H<sub>8</sub> 1.5078(18) Å;<sup>[11]</sup> O=C(CH<sub>3</sub>)<sub>2</sub> 1.478(4) Å).<sup>[12]</sup> Whereas slightly longer C<sub>C=O</sub>–C<sub>cis</sub> bonds are calculated than for the C<sub>C=O</sub>–C<sub>trans</sub> bonds, the experimental C<sub>C=O</sub>–C bond distances in each protonated ketone are the same within 3σ.

The oxonium cations [HO=C<sub>10</sub>H<sub>14</sub>]<sup>+</sup> and [HO=C<sub>5</sub>H<sub>8</sub>]<sup>+</sup> in the [AsF<sub>6</sub>]<sup>–</sup> salts exhibit strong hydrogen bonds to a F atom of the [AsF<sub>6</sub>]<sup>–</sup> anion. The O...F distance in [HO=C<sub>10</sub>H<sub>14</sub>]<sup>+</sup> (O...F(1) 2.6233(16) Å) is larger than [HO=C<sub>5</sub>H<sub>8</sub>]<sup>+</sup> (O...F(1) 2.560(3) Å), however, both are comparable to previously reported hydrogen bonds in protonated cyclopropylcarbiny derivatives (O...F 2.557(6) and 2.601(6) Å).<sup>[2d]</sup> These hydrogen bonds result in an elongation of the As–F(1) distance and an ensuing distortion of the idealized octahedral geometry of the anion. The [HO=C<sub>5</sub>H<sub>8</sub>][AsF<sub>6</sub>] and [HO=C<sub>5</sub>H<sub>8</sub>][SbF<sub>6</sub>] salts are isostructural with cation [HO=C<sub>5</sub>H<sub>8</sub>]<sup>+</sup> in both salts exhibiting no difference in the C=O bond length (1.267(2) Å). The [AsF<sub>6</sub>]<sup>–</sup> salt, however, forms stronger hydrogen-bonding interactions (O...F(1) 2.560(3) Å) than in the [SbF<sub>6</sub>]<sup>–</sup> salt (O...F(1) 2.6043(16) Å).

Unlike [HO=C<sub>10</sub>H<sub>14</sub>]<sup>+</sup> and [HO=C<sub>5</sub>H<sub>8</sub>]<sup>+</sup>, the X-ray crystal structure of [HO=C(CH<sub>3</sub>)<sub>2</sub>][SbF<sub>6</sub>] crystallized in the *P* $\bar{1}$  space group with two crystallographically unique cations and three different anion environments in the unit cell. One of the three

$[\text{SbF}_6]^-$  anions does not have any significant contacts with the oxonium cation, whereas the other two anions accept one or two hydrogen-bonds from  $[\text{HO}=\text{C}(\text{CH}_3)_2]^+$  cations.

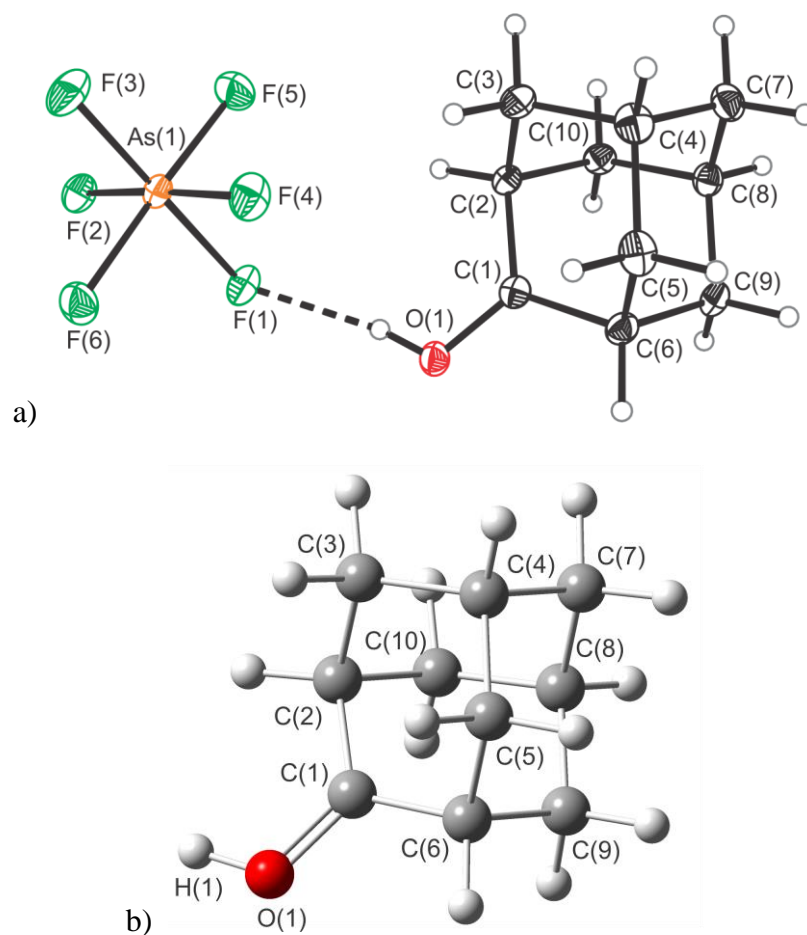

Figure 5.2 a) Thermal ellipsoid plot of  $[\text{HO}=\text{C}_{10}\text{H}_{14}][\text{AsF}_6]$ . Thermal ellipsoids are set at the 50% probability level. b) Geometry-optimized gas-phase structure of  $[\text{HO}=\text{C}_{10}\text{H}_{14}]^+$  at the B3LYP/aug-cc-pVTZ level of theory.

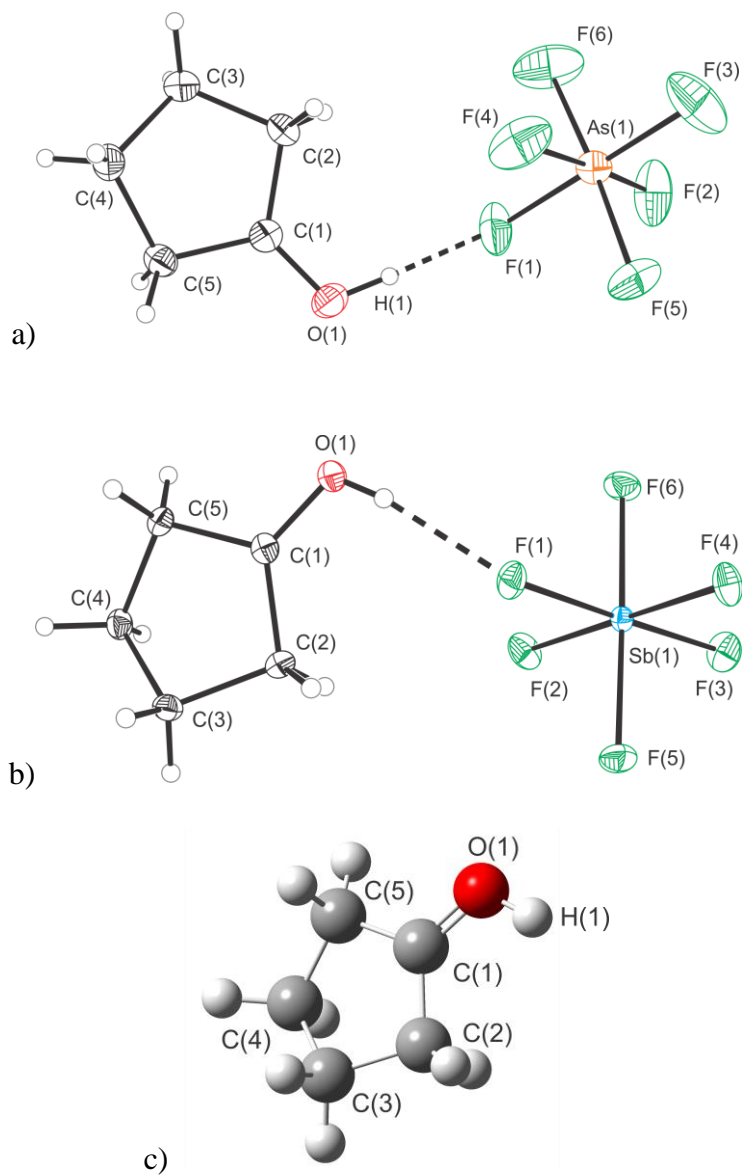

Figure 5.3 Thermal ellipsoid plots of a)  $[\text{HO}=\text{C}_5\text{H}_8][\text{AsF}_6]$ , and b)  $[\text{HO}=\text{C}_5\text{H}_8][\text{SbF}_6]$ . Thermal ellipsoids are set at the 50% probability level. c) Geometry-optimized gas-phase structure of  $[\text{HO}=\text{C}_5\text{H}_8]^+$  at the B3LYP/aug-cc-pVTZ level of theory.

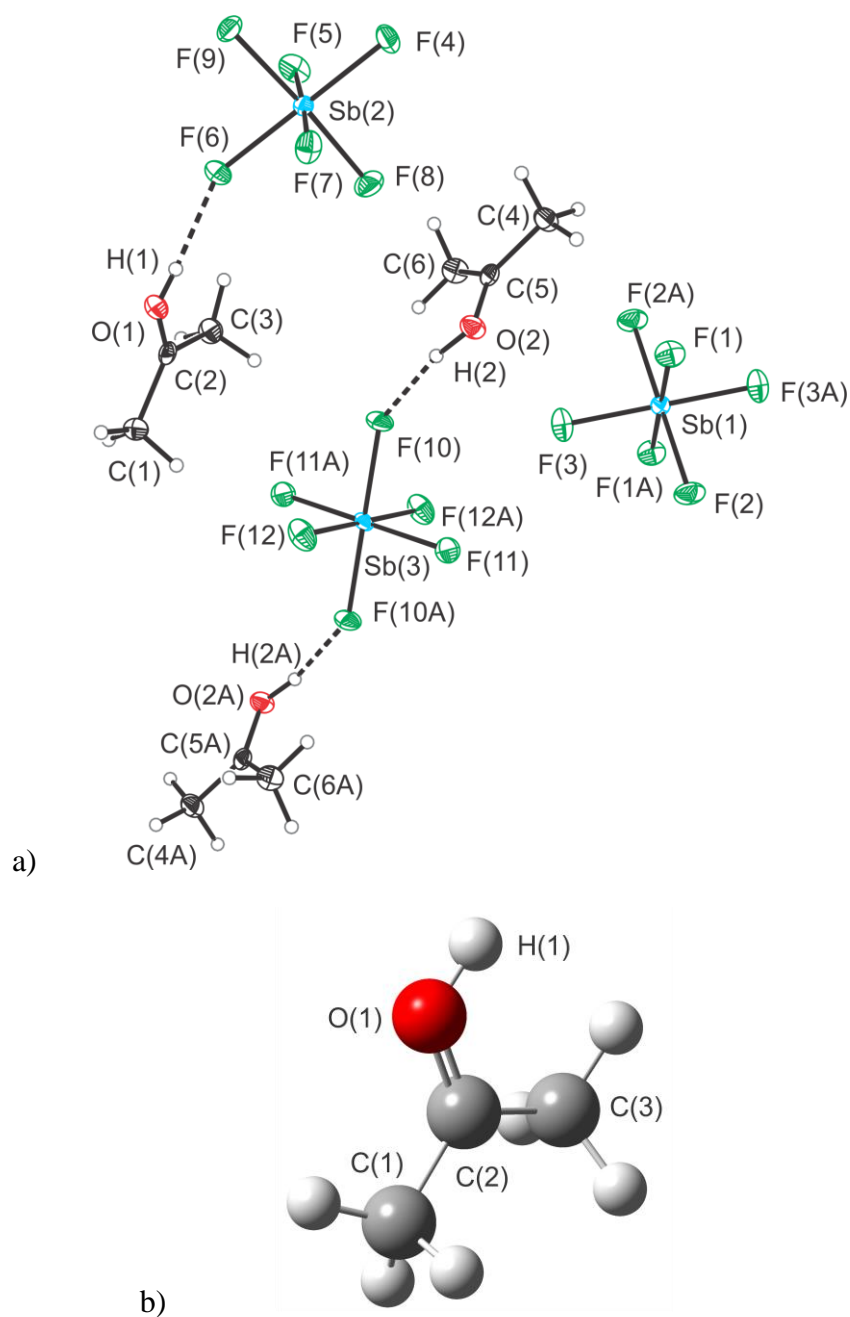

Figure 5.4 Thermal ellipsoid plots of  $[\text{HO}=\text{C}(\text{CH}_3)_2][\text{SbF}_6]$ . Thermal ellipsoids are set at the 50% probability level. b) Geometry-optimized gas-phase structure of  $[\text{HO}=\text{C}(\text{CH}_3)_2]^+$  at the B3LYP/aug-cc-pVTZ level of theory.

Crystals of  $[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_2]_3[\text{HO}=\text{C}(\text{CH}_3)_2]_3[\text{SbF}_6]_5\text{F}$  were grown from aHF at  $-60\text{ }^\circ\text{C}$  and crystallized in the  $P2_1/n$  space group. The asymmetric unit consists of three protonated acetone cations, three hemiprotonated acetone cations, five  $[\text{SbF}_6]^-$  anions, and a fluoride anion (Figure 5.5). The  $[\text{HO}=\text{C}(\text{CH}_3)_2]^+$  cations are each hydrogen-bonded to the fluoride anion in the centre of the asymmetric unit ( $\text{O}\cdots\text{F}$  2.462(3), 2.444(3), 2.443(3) Å) (see Figure 5.6). As expected, the  $\text{C}=\text{O}$  bond distances of the three  $[\text{HO}=\text{C}(\text{CH}_3)_2]^+$  cations are longer (1.259(4), 1.255(4), 1.253(4) Å) and the  $\text{C}-\text{C}$  bonds are shorter relative to neutral acetone (Table 5.3). However, these  $\text{C}=\text{O}$  bond distances are significantly shorter than the aforementioned monoprotonated ketones by upwards of 0.021 Å. This is a result of the hydrogen bonds being stronger than those present in  $[\text{HO}=\text{C}_{10}\text{H}_{14}][\text{AsF}_6]$ ,  $[\text{HO}=\text{C}_5\text{H}_8][\text{AsF}_6]$ ,  $[\text{HO}=\text{C}_5\text{H}_8][\text{SbF}_6]$ , and  $[\text{HO}=\text{C}(\text{CH}_3)_2][\text{SbF}_6]$  causing the elongation of the  $\text{C}=\text{O}$  bond to be less drastic.

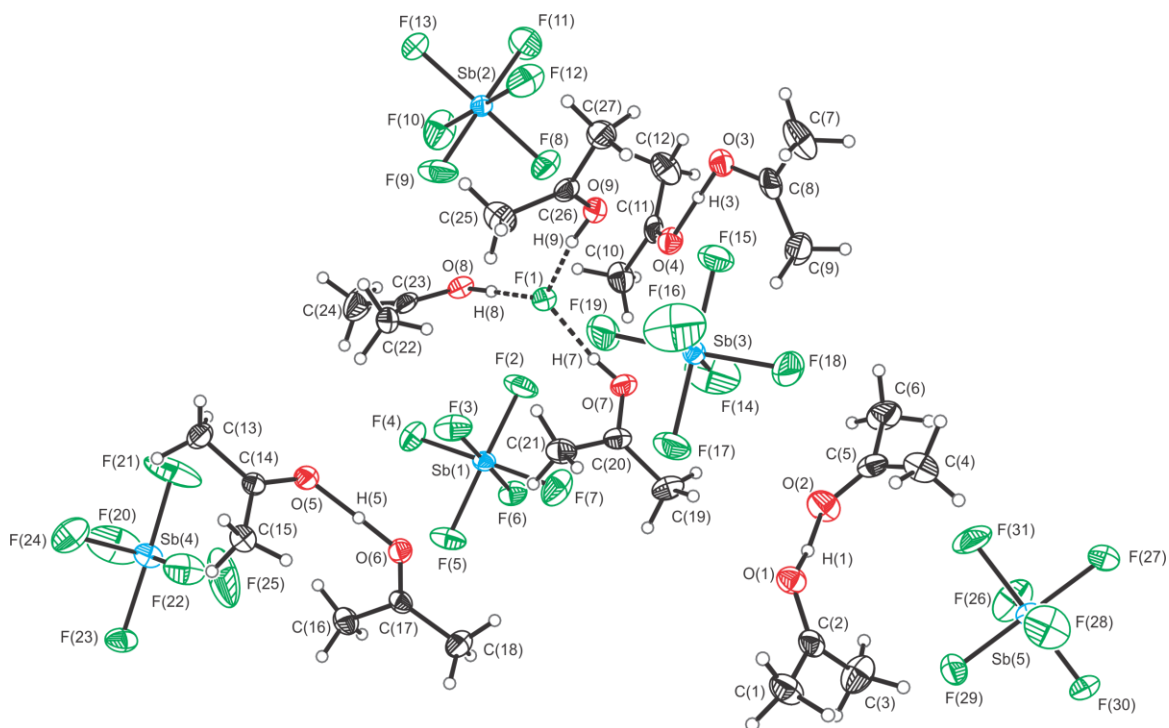

Figure 5.5 Thermal ellipsoid plots of the asymmetric unit  $[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_2]_3[\text{HO}=\text{C}(\text{CH}_3)_2]_3[\text{SbF}_6]_5\text{F}$ . Thermal ellipsoids are set at the 50% probability level.

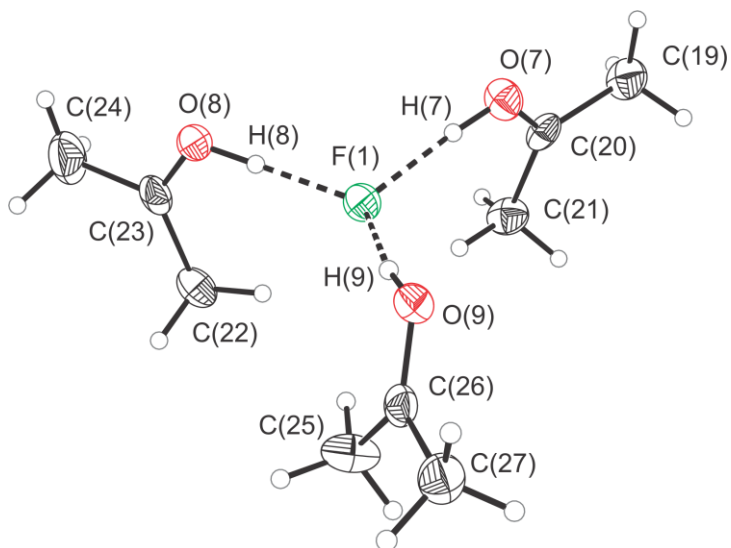

Figure 5.6 Thermal ellipsoid plots of the  $[\text{HO}=\text{C}(\text{CH}_3)_2]_3\text{F}$  unit in the  $[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_2]_3[\text{HO}=\text{C}(\text{CH}_3)_2]_3[\text{SbF}_6]_5\text{F}$  salt. Thermal ellipsoids are set at the 50% probability level.

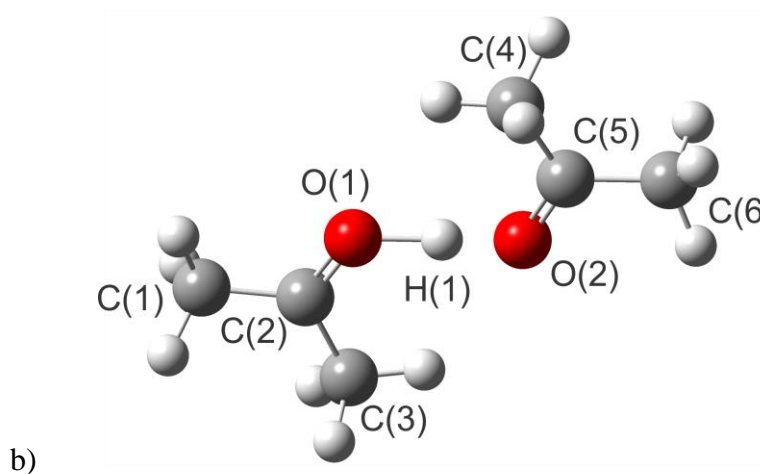

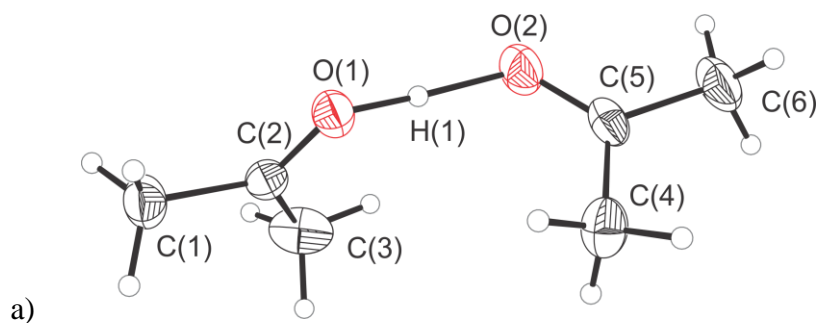

Figure 5.7 Thermal ellipsoid plots of one of three  $[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_2]^+$  cations in the  $[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_2]_3[\text{HO}=\text{C}(\text{CH}_3)_2]_3[\text{SbF}_6]_5\text{F}$  salt. Thermal ellipsoids are set at the 50% probability level.

Table 5.3 Selected Experimental and Calculated Bond Lengths (Å) of Oxonium Cations  $[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_2]^+$  and  $[\text{HO}=\text{C}(\text{CH}_3)_2]^+$  in the  $[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_2]_3[\text{HO}=\text{C}(\text{CH}_3)_2]_3[\text{SbF}_6]_5\text{F}$  salt.

[a] Refers to the carbon *cis* or *trans* to the proton on the oxygen; [b] DFT calculations at the B3LYP/aug-cc-pVTZ level of theory.

The three hemiprotonated acetone cations,  $[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_2]^+$ , show two acetone molecules bridged by a proton and, unlike the monoprotonated species, have no contacts with the anions (Figure 5.7). The C=O bond distances for each species are the same within  $3\sigma$ . Upon hemiprotonation, the C=O bond distances become elongated and C–C bonds contracted (Table 5.3). The calculated C=O distances of the optimized geometry for the gas-phase structure (1.250 and 1.242 Å) fall within, or just outside, the range of experimental data for the three  $[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_2]^+$  cations (1.236(4)–1.243(4) Å). The O–H–O moieties are asymmetric and have O---O distances (2.450(3), 2.437(3), 2.450(3) Å) comparable to the previously synthesized  $[\text{H}(\text{benzophenone})_2]^+$  (O---O 2.470(3) Å).<sup>[4]</sup> This asymmetric O–H–O bridge is replicated in the calculated structure. The calculated

O–H distances (1.15 and 1.27 Å) are slightly larger than the experimental distances likely due to packing effects in the solid state.

### 5.2.3 X-ray Crystallography of Hemiprotonated Aldehydes

The crystallographic parameters and details for hemiprotonated aldehydes  $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2][\text{SbF}_6]$  and  $[\text{H}(\text{O}=\text{CHCH}_3)_2][\text{SbF}_6]$  are provided in Table 5.4. A summary of selected experimental and calculated bond lengths are listed in Table 5.5. A full list experimental and calculated bond lengths and bond angles of the protonated aldehydes can be found in Appendix Tables A.2.8–A.2.11.

[a] from Ref. 16; [b] from Ref. 17; [c] DFT calculations at the B3LYP/cc-pVTZ level of theory.

[d] DFT calculations at the B3LYP/aug-cc-pVTZ level of theory.

The X-ray crystal structures of the  $[\text{SbF}_6]^-$  salts of hemiprotonated aldehydes  $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2][\text{SbF}_6]$  and  $[\text{H}(\text{O}=\text{CHCH}_3)_2][\text{SbF}_6]$  reveal the hydrogen-bridged dimeric nature of the oxonium cations, which contrasts that of the monoprotinated ketones discussed in Section 5.2.2. Hydrogen-bridged dimeric cations were previously observed by X-ray crystallography for benzannelated 2-hydroxyhomotropylium<sup>[3]</sup> and  $[\text{H}(\text{O}=\text{CPh}_2)_2]^+$  cations,<sup>[4]</sup> as well as for acetone, according to IR spectroscopy.<sup>[15]</sup> The cations  $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2]^+$  and  $[\text{H}(\text{O}=\text{CHCH}_3)_2]^+$  are isolated, having no contacts with the anions in the unit cell. In the X-ray crystal structure of  $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2][\text{SbF}_6]$  (Figure 5.8), the  $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2]^+$  cation is comprised of two symmetry-related hydrogen-bridged benzaldehyde molecules (O(1)–H(1) 1.213(3) Å, O(1)---O(1A) 2.425(4) Å). The previously synthesized  $[\text{H}(\text{O}=\text{CPh}_2)_2]^+$  cation shows a similar O---O distance (2.470(3) Å)

to  $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2]^+$ , however, the O–H–O moiety is asymmetric in the crystal structure.<sup>[4]</sup> Upon hemiprotonation of benzaldehyde, the C=O bond distance increases ( $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2]^+$  1.248(3) Å; O=CHC<sub>6</sub>H<sub>5</sub> 1.212(3) Å) and the C<sub>C=O</sub>–C bond length decreases ( $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2]^+$  1.441(4) Å) when compared to the reported gas-phase electron diffraction data for O=CHC<sub>6</sub>H<sub>5</sub> (1.479(4) Å) (Table 5.5).<sup>[16]</sup>

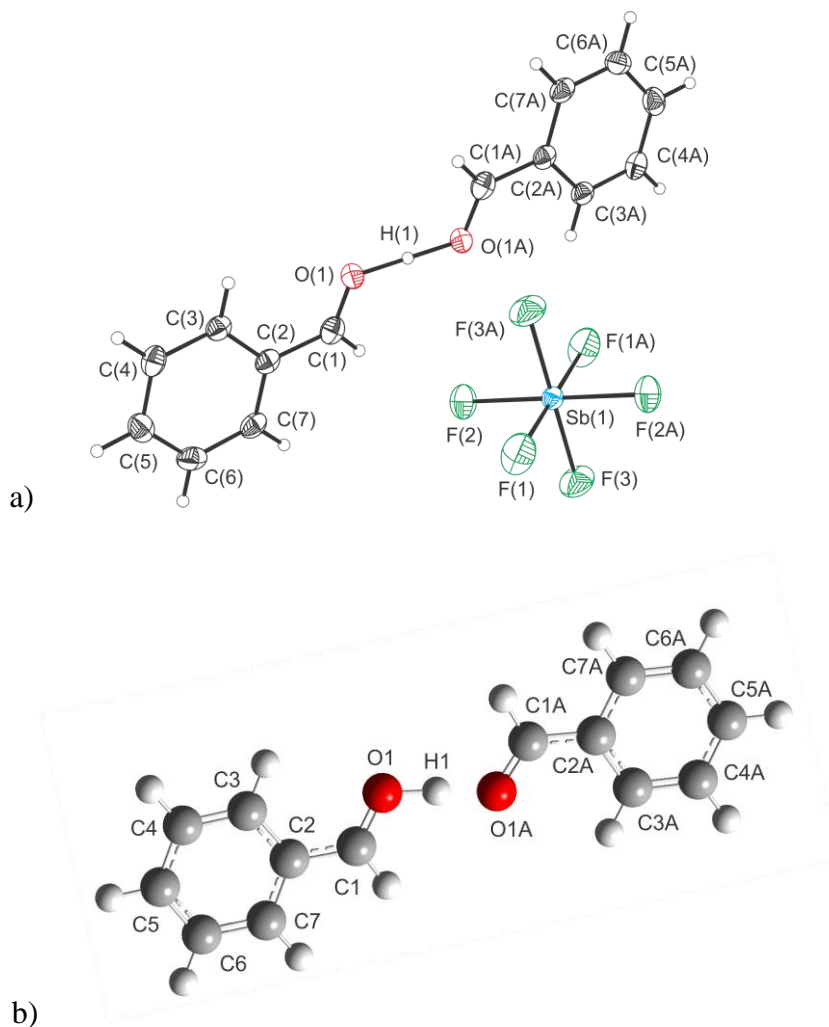

Figure 5.8 a) Thermal ellipsoid plots of  $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2][\text{SbF}_6]$ . Thermal ellipsoids are set at the 50% probability level. b) Geometry-optimized gas-phase structure of  $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2]^+$  at the B3LYP/cc-pVTZ level of theory.

Geometry optimization at the B3LYP/cc-pVTZ level of theory reproduced the planar geometry of  $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2]^+$  and the *E*-configuration of the C=O–H moiety; the hydrogen-bridge is shown to be asymmetric in the gas phase, whereas the symmetric hydrogen bridge in the crystal structure is imposed by crystallographic symmetry. The calculated C=O bond distances (1.256 and 1.246 Å) compare well with the experimental value for  $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2]^+$ , whereas the C–C bond distances are underestimated by the calculations (by up to 0.018 Å), likely due to packing effects in the solid state.

The crystal structure of  $[\text{H}(\text{O}=\text{CHCH}_3)_2][\text{SbF}_6]$  (Figure 5.9) contains a protonated acetaldehyde in the *Z*-configuration that is hydrogen-bonded to a second acetaldehyde molecule in an *E*-configuration. DFT calculations at the B3LYP/aug-cc-pVTZ level of theory showed the configuration of the lowest-energy gas-phase geometry of  $[\text{H}(\text{O}=\text{CHCH}_3)_2]^+$  to be the reverse, suggesting packing effects influence the configuration in the solid state. The *Z*-geometry of the oxonium cation  $[\text{HO}=\text{CHCH}_3]^+$  was calculated to be only 3 kJ/mol higher in energy than *E*- $[\text{HO}=\text{CHCH}_3]^+$  (see Figure 5.10).

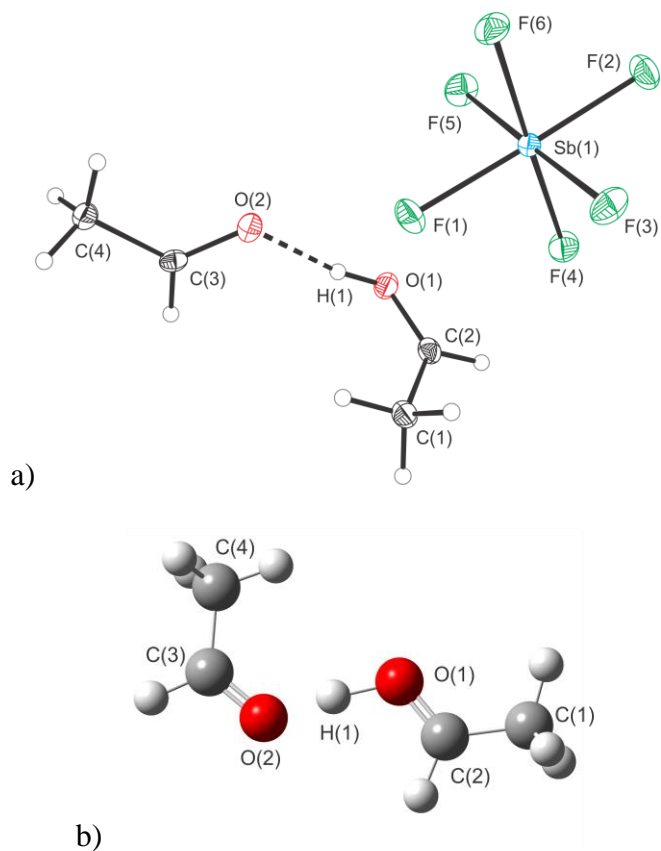

Figure 5.9 a) Thermal ellipsoid plots of  $[\text{H}(\text{O}=\text{CHCH}_3)_2][\text{SbF}_6]$ . Thermal ellipsoids are set at the 50% probability level. b) Geometry-optimized gas-phase structure of  $[\text{H}(\text{O}=\text{CHCH}_3)_2]^+$  at the B3LYP/aug-cc-pVTZ level of theory.

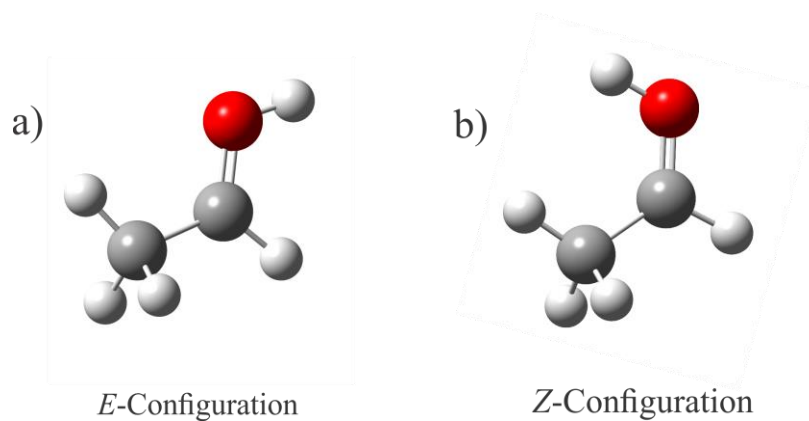

Figure 5.10 Protonated acetaldehyde,  $[\text{HO}=\text{CHCH}_3]^+$ , energies in the a) *E*-configuration,  $E = -404\,862$  kJ/mol, and b) *Z*-configuration,  $E = -404\,859$  kJ/mol. Calculations done at the B3LYP/aug-cc-pVTZ level of theory.

The hydrogen-bond in  $[\text{H}(\text{O}=\text{CHCH}_3)_2]^+$  ( $\text{O}(1)\cdots\text{O}(2)$  2.4449(19) Å) is asymmetric, similar to the hydrogen-bridge observed in  $[\text{H}(\text{O}=\text{C}(\text{CH}_3)_2)_2]^+$  ( $\text{O}(1)\cdots\text{O}(2)$  2.450(3) Å). However, this contrasts with the symmetric hydrogen-bridge in  $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2]^+$  (2.425(4) Å) where the  $\text{O}\cdots\text{O}$  distance is smaller and thus results in a significantly stronger bridging interaction in. Similar to the previous protonated ketones and aldehydes, the  $\text{C}=\text{O}$  bond distance decreases ( $[\text{H}(\text{O}=\text{CHCH}_3)_2]^+$   $\text{C}(2)\text{--}\text{O}(1)$  1.239(2) Å;  $\text{O}=\text{CHCH}_3$  1.208(3) Å) and the  $\text{C}_{\text{C}=\text{O}}\text{--}\text{C}$  bond increases ( $[\text{H}(\text{O}=\text{CHCH}_3)_2]^+$   $\text{C}(2)\text{--}\text{C}(1)$  1.457(3) Å;  $\text{O}=\text{CHCH}_3$  1.514(5) Å) upon protonation (Table 5.5) when compared to a previous electron diffraction study of acetaldehyde.<sup>[17]</sup> Interestingly, the second acetaldehyde in the asymmetric unit appears to be almost equally affected by the hydrogen-bridge. The small difference in  $\text{C}=\text{O}$  bond lengths in the two acetaldehyde moieties is reproduced by the geometry optimization.

#### 5.2.4 Raman Spectroscopy of Protonated 2-Adamantanone, Cyclopentanone, Acetone, Benzaldehyde, and Acetaldehyde

The low-temperature Raman spectra of the protonated ketone and aldehyde salts (excluding  $[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_2]_3[\text{HO}=\text{C}(\text{CH}_3)_2]_3[\text{SbF}_6]_5\text{F}$ ) were recorded at  $-100^\circ\text{C}$  and are depicted in Figures 5.11–5.15. Vibrational frequencies of the geometry-optimized cations were calculated and used to aid in the assignments of the Raman bands. The full analysis and assignments of the Raman spectra can be found in Appendix Tables A.2.12–A.2.17.

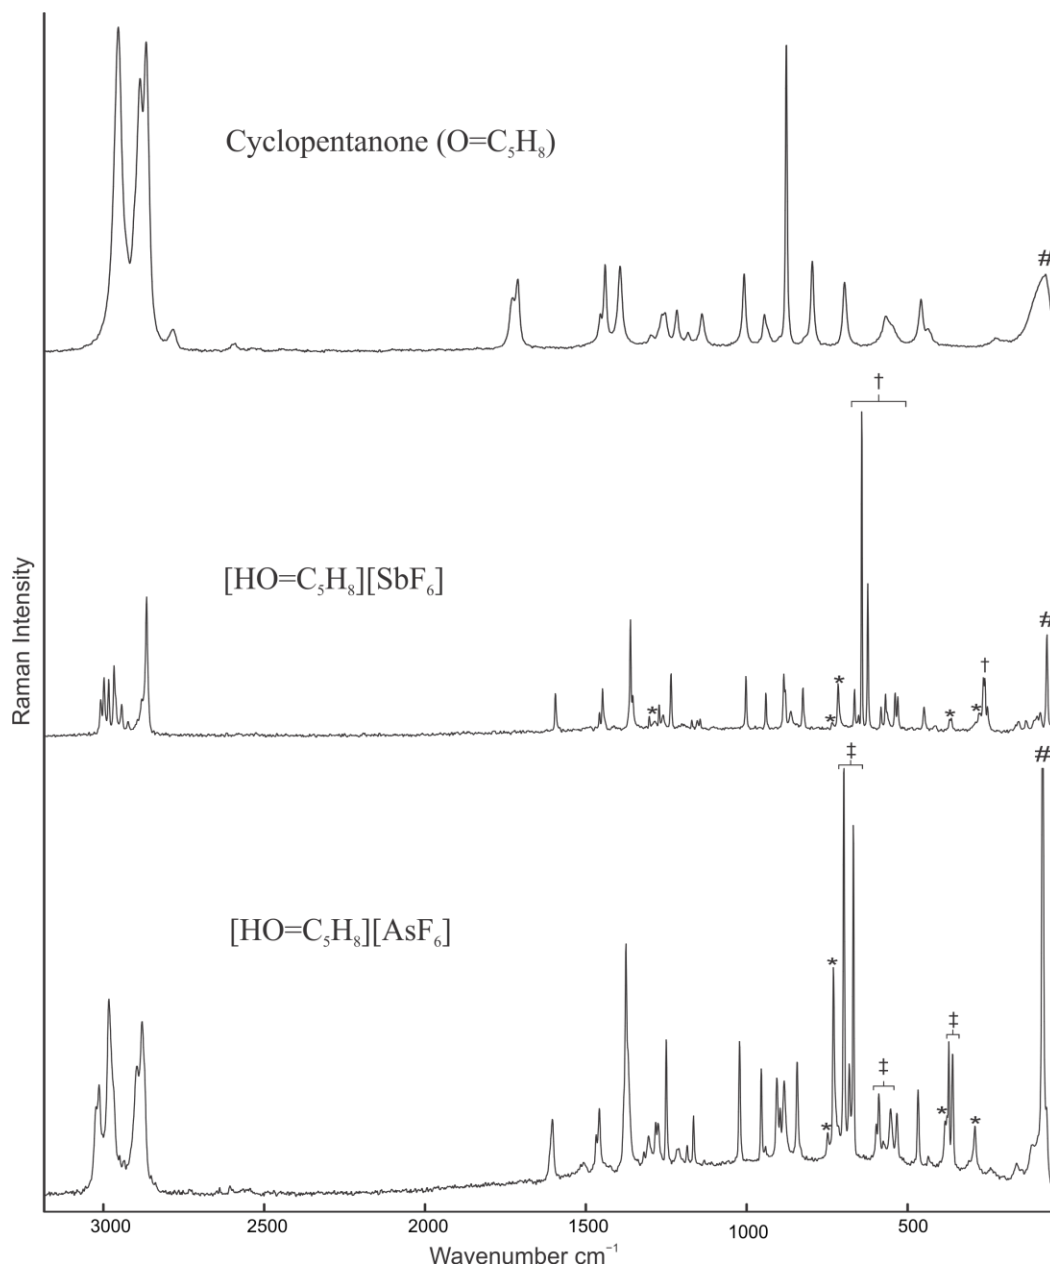

Figure 5.12 Raman spectrum of  $\text{O}=\text{C}_5\text{H}_8$ ,  $[\text{HO}=\text{C}_5\text{H}_8][\text{SbF}_6]$ , and  $[\text{HxO}=\text{C}_5\text{H}_8][\text{AsF}_6]$  at  $-100^\circ\text{C}$ . Symbols denote bands arising from FEP sample tube (\*), an instrumental artifact (#),  $[\text{SbF}_6]^-$  vibrations (†), and  $[\text{AsF}_6]^-$  vibrations (‡).

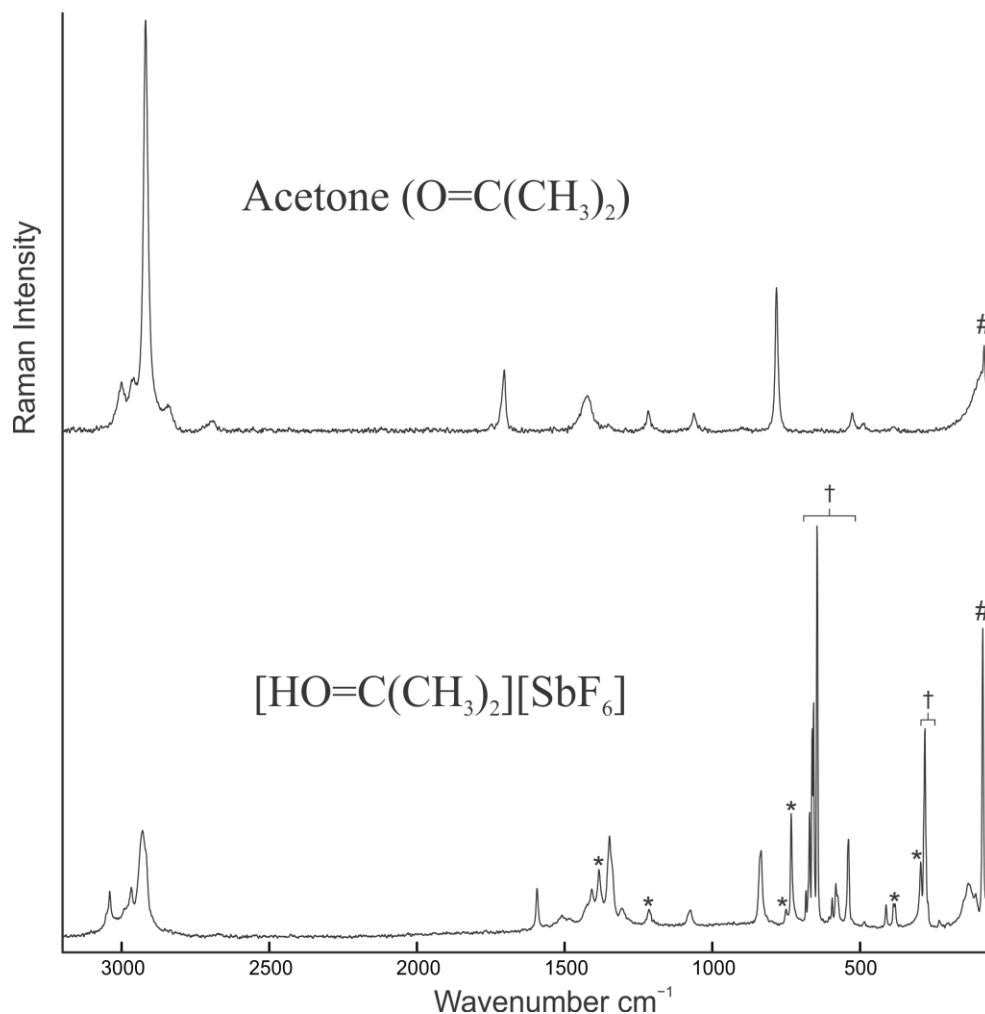

Figure 5.13 Raman spectrum of  $\text{O}=\text{C}(\text{CH}_3)_2$  and  $[\text{HO}=\text{C}(\text{CH}_3)_2][\text{SbF}_6]$  at  $-100\text{ }^\circ\text{C}$ . Symbols denote bands arising from FEP sample tube (\*), an instrumental artifact (#), and  $[\text{SbF}_6]^-$  vibrations (†).

Protonation of the ketones and aldehydes was accompanied by a dramatic decrease in the characteristic C=O stretching frequency. A comparison of the  $\nu(\text{CO})$  stretching frequencies can be found in Table 5.6. For monoprotonated ketones  $[\text{HO}=\text{C}_{10}\text{H}_{14}]^+$ ,  $[\text{HO}=\text{C}_5\text{H}_8]^+$ , and  $[\text{HO}=\text{C}(\text{CH}_3)_2]^+$ , the C=O stretching frequencies decreased between 116 and  $155\text{ cm}^{-1}$  relative to the neutral parent compounds, which was in agreement with a previous LT-IR study of  $[\text{HO}=\text{C}(\text{CH}_3)_2][\text{SbF}_6]$ .<sup>[15]</sup> This reflects a weakening of the C=O

bond. DFT calculations at the B3LYP/aug-cc-pVTZ level of theory overestimated the decrease in the C=O stretching frequencies upon protonation (194 to 224  $\text{cm}^{-1}$ ), consistent with the absence of H-bonding in the computed gas-phase structures. Due to the high degree of splitting and coupling of the bands in the Raman spectra, trends in the  $\nu(\text{CCC})$  stretching region could not easily be determined. With the aid of DFT calculations, the  $\nu(\text{CCC})$  stretching frequency and ring breathing modes of the ketones increased upon protonation. There was an increase in the  $\nu(\text{CCC})$  stretching frequency of acetone from 788  $\text{cm}^{-1}$  to 835  $\text{cm}^{-1}$  upon protonating the carbonyl group. The ring breathing modes of 2-adamantanone, 717  $\text{cm}^{-1}$ , and cyclopentanone, 811  $\text{cm}^{-1}$ , increased upon protonating the carbonyl group to 743 and 898  $\text{cm}^{-1}$ , respectively. This increase in frequency complimented the decrease in bond lengths of the *cis* and *trans* C–C bonds and subsequent increase in bond strength.

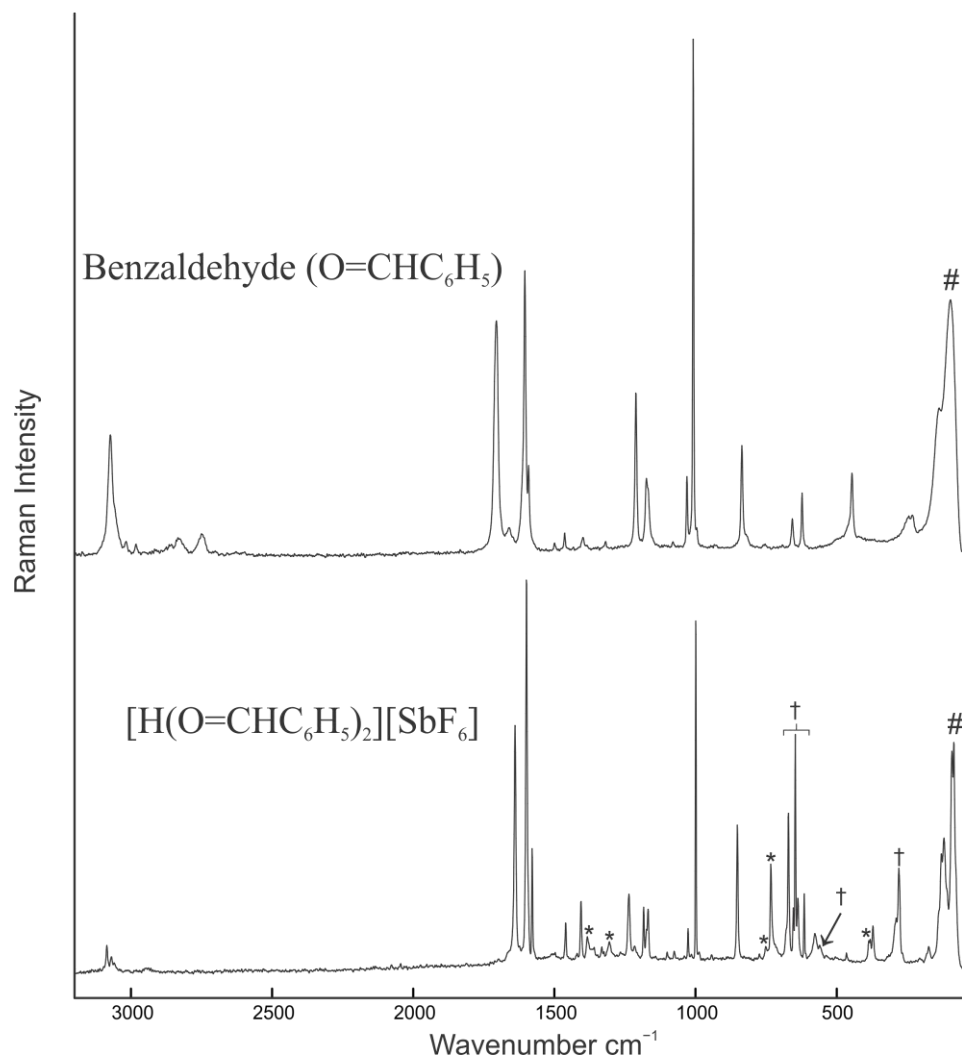

Figure 5.14 Raman spectrum of  $\text{O=CHC}_6\text{H}_5$  and  $[\text{H}(\text{O=CHC}_6\text{H}_5)_2][\text{SbF}_6]$  at  $-100\text{ }^\circ\text{C}$ . Symbols denote bands arising from FEP sample tube (\*), an instrumental artifact (#), and  $[\text{SbF}_6]^-$  vibrations ( $\dagger$ ).

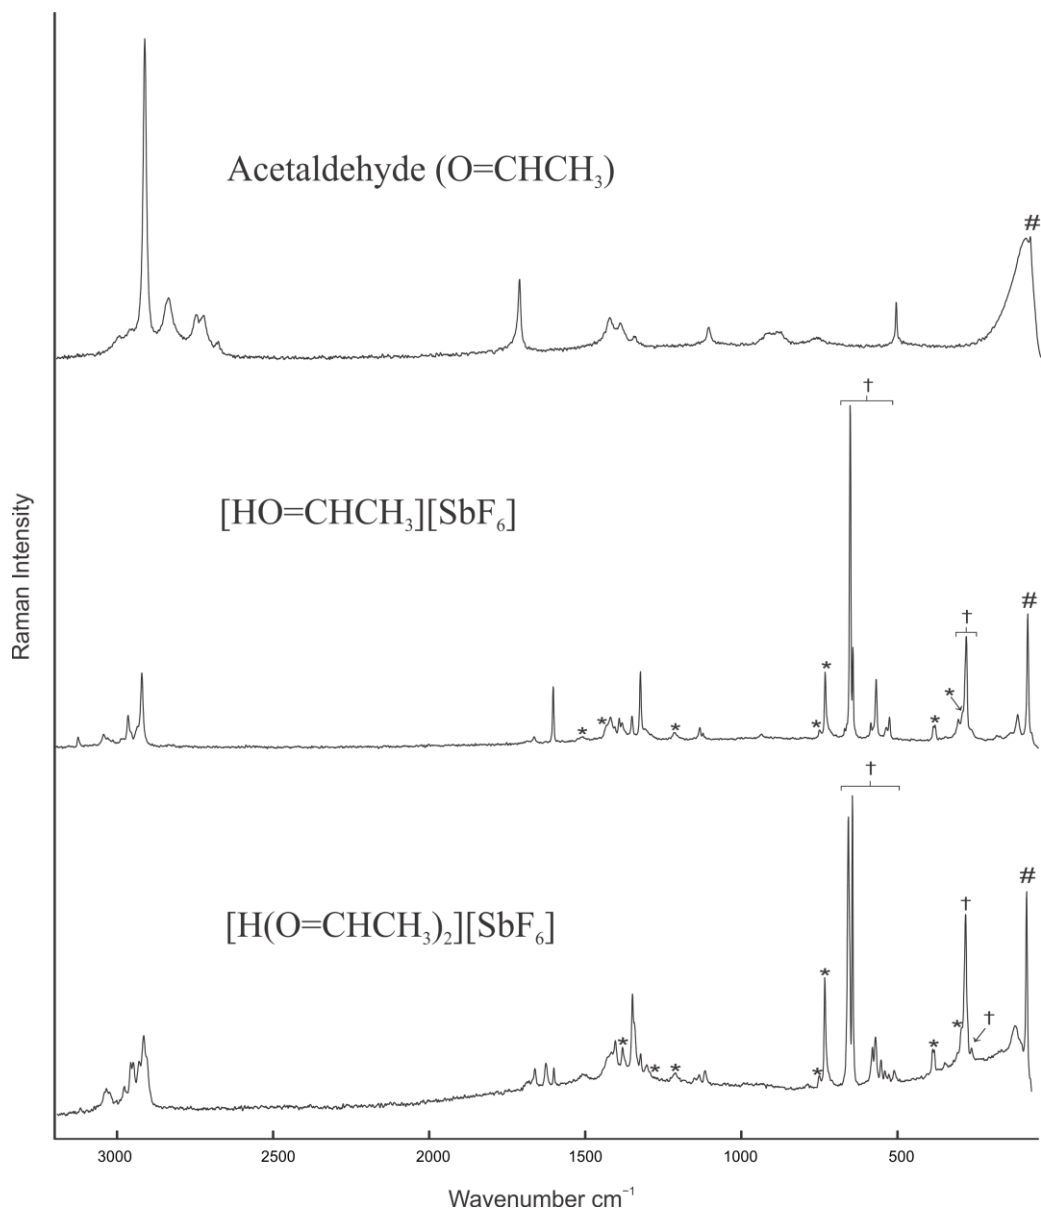

Figure 5.15 Raman spectrum of  $\text{O}=\text{CHCH}_3$ ,  $[\text{HO}=\text{CHCH}_3][\text{SbF}_6]$ , and  $[\text{H}(\text{O}=\text{CHCH}_3)_2][\text{SbF}_6]$  at  $-100\text{ }^\circ\text{C}$ . Symbols denote bands arising from FEP sample tube (\*), an instrumental artifact (#), and  $[\text{SbF}_6]^-$  vibrations (†).

Unlike the protonated ketones, the  $\text{C}=\text{O}$  stretching frequency of  $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2][\text{SbF}_6]$  ( $1639\text{ cm}^{-1}$ ) only decreased by  $59\text{ cm}^{-1}$  relative to  $\text{O}=\text{CHC}_6\text{H}_5$ . The Raman spectrum of  $[\text{H}(\text{O}=\text{CHCH}_3)_2][\text{SbF}_6]$  showed two  $\text{C}=\text{O}$  stretching frequencies ( $1665$  and  $1629\text{ cm}^{-1}$ ), which were associated with the protonated and hydrogen-bond

accepting acetaldehyde moieties, respectively, as observed in the crystal structure of  $[\text{H}(\text{O}=\text{CHCH}_3)_2][\text{SbF}_6]$ . The decrease in the C=O stretching frequency by up to  $83\text{ cm}^{-1}$  indicates a decrease in the bond strength similar to the protonated ketones. As expected, the decrease in C=O stretching frequency was more dramatic for the monoprotonated acetaldehyde cation,  $[\text{HO}=\text{CHCH}_3]^+$  ( $108\text{ cm}^{-1}$ ), since there are no bonding interactions with a second acetaldehyde. While it is expected that the ring modes of hemiprotonated benzaldehyde and C–C stretches of acetaldehyde increased, this could not be confidently confirmed due to the high degree of coupling and splitting of the Raman bands.

### 5.2.5 Computational Results

Density functional theory (DFT) calculations at the B3LYP/aug-cc-pVTZ level of theory were carried out on the protonated cations previously discussed along with their parent compounds. This level of theory was chosen as it provides reliable structural information (see Chapter 2, Section 2.11 for method validation). Vibrational frequencies along with IR and Raman intensities were calculated. The DFT-optimized gas-phase geometries of the oxonium cations as well as their parent ketones, generally show excellent agreement with the experimental values (*vide supra*).

Natural bond order (NBO) analyses were carried out to investigate the bonding in these protonated ketones and aldehydes (Appendix Tables A.2.18–A.2.22). A summary of the NBO analysis is found in Table 5.7. For acetone, the Natural Population Analysis (NPA) charge on the carbonyl carbon increased from 0.59 to 0.73 when protonated, while the charge on oxygen did not change appreciably. When protonated, the C=O bond order in acetone decreased from 1.83 to 1.39, reflecting the significant weakening of the bond,

which is paralleled by the increase in C=O bond length and lowering of the C=O stretching frequency. The NPA charges of the hemiprotonated acetone cation (0.70 and 0.68) were slightly lower on the carbon of the carbonyl compared with  $[\text{HO}=\text{C}(\text{CH}_3)_2]^+$ . The bond order of  $[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_2]^+$  (1.53 and 1.58) is in between  $[\text{HO}=\text{C}(\text{CH}_3)_2]^+$  and the parent compound, consistent with its slightly shorter C=O bond length. Similar trends were found for the monoprotonated cyclopentanone and 2-adamantanone systems. Protonation of cyclopentanone and 2-adamantanone resulted in an increase of the NPA charge on the carbon of the C=O group from 0.60 to 0.74 and 0.61 to 0.74, respectively. The bond order of C=O decreased from 1.84 to 1.39 for cyclopentanone and 1.83 to 1.35 for 2-adamantanone, very similar to acetone.

NBO analyses for  $\text{O}=\text{CHCH}_3$ ,  $[\text{HO}=\text{CHCH}_3]^+$ , and  $[\text{H}(\text{O}=\text{CHCH}_3)_2]^+$  showed the expected decrease in the C=O bond order from  $\text{O}=\text{CHCH}_3$  (1.88) to protonated acetaldehyde,  $[\text{HO}=\text{CHCH}_3]^+$  (1.47), with that of hemiprotonated  $[\text{H}(\text{O}=\text{CHCH}_3)_2]^+$  being intermediate (1.61 and 1.65). Similarly, hemiprotonation of benzaldehyde decreased the C=O bond order from 1.82 to 1.48 and 1.54 in  $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2]^+$ . The NPA charge on the carbon of the carbonyl in acetaldehyde is 0.44 and increased to 0.53 and 0.54 in  $[\text{H}(\text{O}=\text{CHCH}_3)_2]^+$  and 0.57 in  $[\text{HO}=\text{CHCH}_3]^+$ . The NPA charge of this carbon in the benzaldehyde system did not show as large of a difference upon hemiprotonation ( $\text{O}=\text{CHC}_6\text{H}_5$  0.41;  $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2]^+$  0.45 and 0.45). This may be a result of the ability of the conjugated benzene rings to delocalize the positive charge upon formation of the hemiprotonated benzaldehyde dimer cation.

Table 5.7 Selected NPA Charges, Valences and Wiberg Bond Indices of the Oxonium Cations and their Parent Compounds.

	NPA Charges (Valences <sup>[a]</sup> )	NPA Charges (Valences <sup>[a]</sup> )	Wiberg Bond Indices

<sup>[a]</sup> Sum of the Wiberg Bond Indices per atom.

Formation of these protonated ketones and aldehydes affected the shape and energy of the molecular orbitals (see Appendix Figures A.2.1–A.2.8). Using acetone as a representative example for the protonated ketones, Figure 5.14 shows the HOMO and LUMO of acetone and protonated acetone, and their corresponding energies. The energy of the LUMO was dramatically lowered from −18 kJ/mol to −189 kJ/mol, and even lower to −596 kJ/mol for hemiprotonated acetone, making the carbonyl more accessible for nucleophilic attack upon protonation (Table 5.8). This reflects the increased reactivity of protonated carbonyl compounds as proposed intermediates in acid-catalyzed reactions.

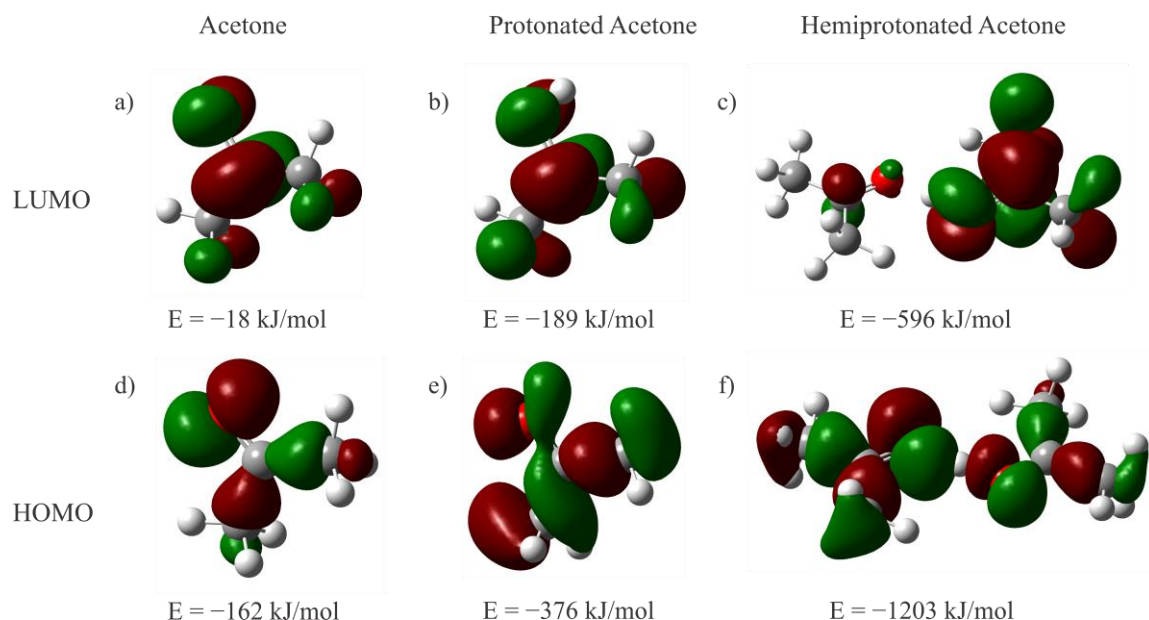

Figure 5.16 Molecular orbitals of acetone, protonated acetone, and hemiprotonated acetone. a) LUMO of acetone with  $E = -18$  kJ/mol; b) LUMO of protonated acetone with  $E = -189$  kJ/mol; c) LUMO of hemiprotonated acetone with  $E = -596$  kJ/mol; d) HOMO of acetone with  $E = -162$  kJ/mol; e) HOMO of protonated acetone with  $E = -376$  kJ/mol; f) HOMO of hemiprotonated acetone with  $E = -1203$  kJ/mol.

Table 5.8 Calculated Energies (kJ/mol) of the HOMO and LUMO for the Protonated Ketones,  $[\text{HO}=\text{C}_{10}\text{H}_{14}]^+$ ,  $[\text{HO}=\text{C}_5\text{H}_8]^+$ ,  $[\text{HO}=\text{C}(\text{CH}_3)_2]^+$ , and  $[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_2]^+$ .

Compound	HOMO Energy	LUMO Energy
$\text{O}=\text{C}_{10}\text{H}_{14}$	-151	-13
$[\text{HO}=\text{C}_{10}\text{H}_{14}]^+$	-286	-163
$\text{O}=\text{C}_5\text{H}_8$	-157	-20
$[\text{HO}=\text{C}_5\text{H}_8]^+$	-323	-182
$\text{O}=\text{C}(\text{CH}_3)_2$	-162	-18
$[\text{HO}=\text{C}(\text{CH}_3)_2]^+$	-376	-189
$[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_2]^+$	-1203	-596

A substantial decrease in the energy of the HOMO was also observed from  $-162$  kJ/mol to  $-376$  kJ/mol, and  $-1203$  kJ/mol for hemiprotonated acetone, reducing the accessibility to electrophilic attack upon forming the O–H bond. A similar drop in energy of the LUMO and HOMO was observed for  $[\text{HO}=\text{C}_{10}\text{H}_{14}]^+$  and  $[\text{HO}=\text{C}_5\text{H}_8]^+$  cations (Table 5.8).

Table 5.9 Calculated Energies (kJ/mol) of the HOMO and LUMO for the Protonated Aldehydes,  $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2]^+$ ,  $[\text{H}(\text{O}=\text{CHCH}_3)_2]^+$ , and  $[\text{HO}=\text{CHCH}_3]^+$ .

Compound	HOMO Energy	LUMO Energy
$\text{O}=\text{CHC}_6\text{H}_5$	-697	-196
$[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2]^+$	-1021	-621
$\text{O}=\text{CHCH}_3$	-216	-157
$[\text{HO}=\text{CHCH}_3]^+$	-382	-201
$[\text{H}(\text{O}=\text{CHCH}_3)_2]^+$	-1270	-664

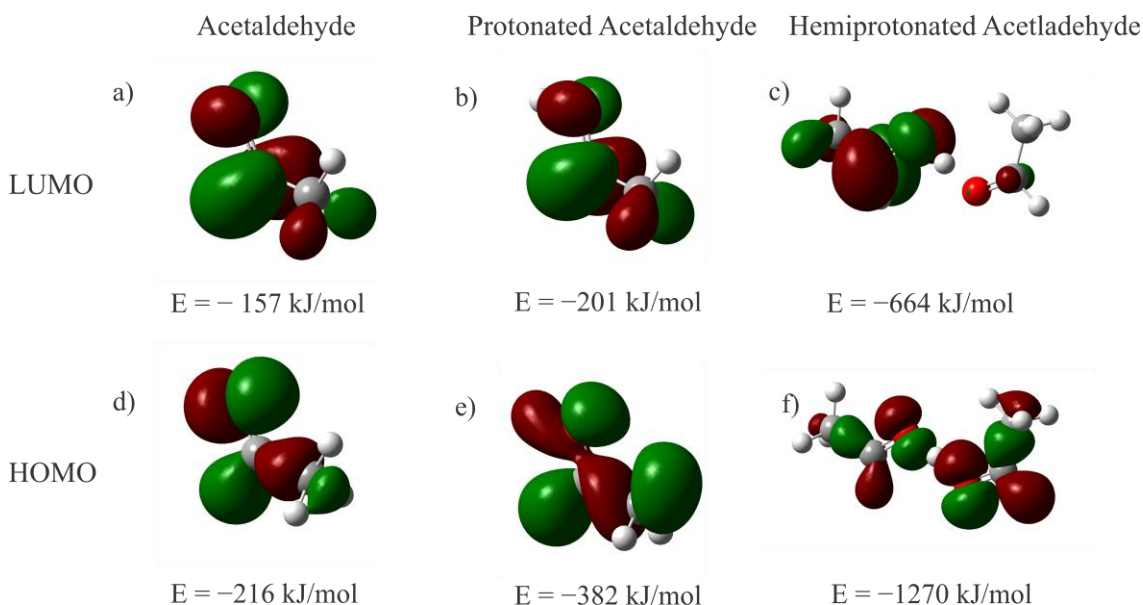

Figure 5.17 Molecular orbitals of acetaldehyde and protonated acetaldehyde. a) LUMO of acetaldehyde with  $E = -157 \text{ kJ/mol}$ ; b) LUMO of protonated acetaldehyde with  $E = -201 \text{ kJ/mol}$ ; c) LUMO of hemiprotonated acetaldehyde with  $E = -664 \text{ kJ/mol}$ ; d) HOMO of acetaldehyde with  $E = -216 \text{ kJ/mol}$ ; e) HOMO of protonated acetaldehyde with  $E = -382 \text{ kJ/mol}$ ; f) HOMO of hemiprotonated acetaldehyde with  $E = -1270 \text{ kJ/mol}$ .

The HOMO and LUMO of acetaldehyde, protonated acetaldehyde, and hemiprotonated acetaldehyde are shown in Figure 5.14. The decrease in energy between the LUMO of acetaldehyde and protonated acetaldehyde,  $[\text{HO}=\text{CHCH}_3]^+$ , was  $44 \text{ kJ/mol}$  (Table 5.9). This change in energy was not as large when compared to the protonation of acetone where the energy difference was  $171 \text{ kJ/mol}$ . The two methyl groups in acetone

provide more steric hinderance making it less prone towards nucleophilic attack compared to acetaldehyde. This results in acetone being less reactive in acid-catalyzed reactions compared to acetaldehyde. The energy of the LUMO of hemiprotonated acetaldehyde,  $[\text{H}(\text{O}=\text{CHCH}_3)_2]^+$  ( $-664$  kJ/mol) was even lower compared to the monoprotonated compound ( $-201$  kJ/mol). Despite the NPA charge of the carbon of the carbonyl group for  $[\text{H}(\text{O}=\text{CHCH}_3)_2]^+$  being slightly lower than  $[\text{HO}=\text{CHCH}_3]^+$  (Table 5.7), the lower LUMO energy suggests the reactivity of  $[\text{H}(\text{O}=\text{CHCH}_3)_2]^+$  is much higher than  $[\text{HO}=\text{CHCH}_3]^+$ . Hemiprotonation of benzaldehyde also led to a large decrease in the energy of the HOMO (by  $324$  kJ/mol) and LUMO (by  $425$  kJ/mol), as expected from the previous two hemiprotonated cations.

### 5.3 Summary and Conclusions

In conclusion, the cations presented in this study are the first examples of representative protonated ketones and aldehydes to be isolated and structurally characterized in the solid state. Salts of  $[\text{HO}=\text{C}_{10}\text{H}_{14}][\text{AsF}_6]$ ,  $[\text{HO}=\text{C}_5\text{H}_8][\text{AsF}_6]$ ,  $[\text{HO}=\text{C}_5\text{H}_8][\text{SbF}_6]$  and  $[\text{HO}=\text{C}(\text{CH}_3)_2][\text{SbF}_6]$  were found to be stable at RT and characterized by Raman spectroscopy and single-crystal X-ray diffraction. X-ray crystallography has shown the  $[\text{HO}=\text{C}_{10}\text{H}_{14}]^+$ ,  $[\text{HO}=\text{C}_5\text{H}_8]^+$ , and  $[\text{HO}=\text{C}(\text{CH}_3)_2]^+$  cations to contain hydrogen bonds with their respective anions aiding in their thermal stability at RT. This is especially the case for the  $[\text{HO}=\text{C}(\text{CH}_3)_2][\text{SbF}_6]$  salt which was stable for 1 h before signs of decomposition were observed by Raman spectroscopy. The protonation of these ketones resulted in an increase in the C=O bonds and decrease in the *cis* and *trans* C–C bonds relative to their parent compounds.

The X-ray crystal structure of hemiprotonated acetone was obtained for the first time. The complex salt of  $[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_2]_3[\text{HO}=\text{C}(\text{CH}_3)_2]_3[\text{SbF}_6]_5\text{F}$  showed two different cation environments: the isolated  $[\text{H}(\text{O}=\text{C}(\text{CH}_3)_2)_2]^+$  cations and the  $[\text{HO}=\text{C}(\text{CH}_3)_2]^+$  cations having hydrogen bonding interactions with a lone fluoride anion. The crystal structure revealed  $[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_2]^+$  to be a hydrogen-bridged dimer-like cation where the O–H–O moiety is asymmetric with O...O distances of 2.437(3) and 2.450(3) Å.

The protonated aldehydes,  $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2]^+$ ,  $[\text{H}(\text{O}=\text{CHCH}_3)_2]^+$ , and  $[\text{HO}=\text{CHCH}_3]^+$  were isolated for the first time and, unlike the monoprotonated ketones, proved to be much more temperature-sensitive, rapidly decomposing at RT. In the case of benzaldehyde, even using one molar equivalent of aldehyde versus  $\text{SbF}_5$  resulted in the synthesis of the hemiprotonated benzaldehyde dimer. The  $[\text{H}(\text{O}=\text{CHCH}_3)_2][\text{SbF}_6]$  salt could only be obtained in admixture with  $[\text{HO}=\text{CHCH}_3][\text{SbF}_6]$ . The crystal structure of  $[\text{H}(\text{O}=\text{CHCH}_3)_2]^+$  showed a similar asymmetric hydrogen bridge to the hemiprotonated acetone with a distance of 2.4449(19) Å.

The presented experimental and computational results provide key data about a class of intermediates that are ubiquitous in acid-catalysed organic reaction mechanisms. As expected, protonation significantly increases the electrophilicity of the carbonyl carbon, as reflected by bond elongation, significant decrease in the  $\nu(\text{CO})$  stretching frequencies, as well as calculated charges, bond orders, and LUMO energies.

## 6. Lewis Acid-Base Adducts of Ketones with AsF<sub>5</sub>

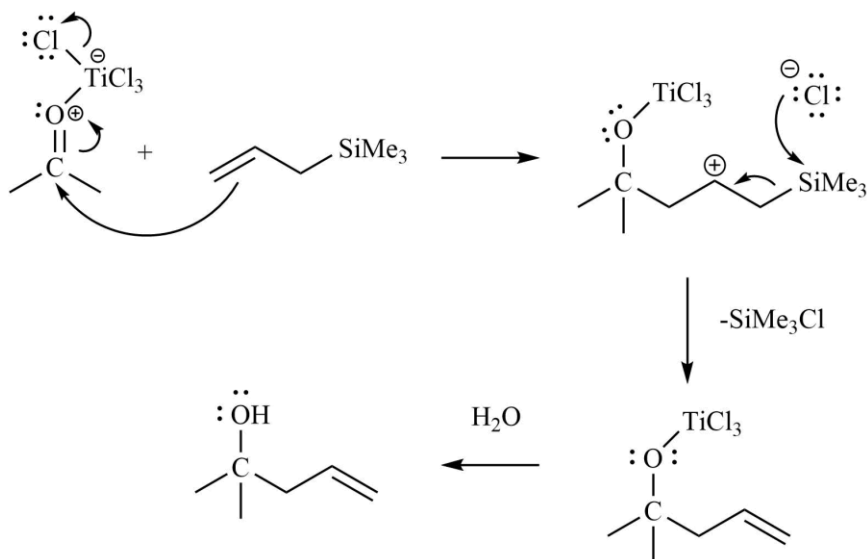

### 6.1 Introduction

Lewis acids are commonly used, mostly as catalysts, in a variety of organic chemistry reactions including Friedel-Crafts (Equation 6.1), Diels-Alder (Equation 6.2), Hosomi-Sakurai (Equation 6.3), and Mukaiyama aldol reactions (Equation 6.4).<sup>[1]</sup>

Lewis acid reagents used in organic chemistry include the readily available AlCl3, TiCl4, BF3, and SnCl4.<sup>[2]</sup> The mechanism involves the binding of the Lewis acid to a Lewis basic substrate, for example a ketone or aldehyde, which is accompanied by withdrawal of electron density from the functional group, such as the C=O group. This lowers the energy of the LUMO making the carbon center more readily accessible for nucleophilic attack.<sup>[3]</sup> The reaction mechanism of the Hosomi-Sakurai reaction is shown as an example in Scheme

6.1 where the Lewis acid  $\text{TiCl}_4$  activates the electrophile allowing for allylation by allyltrimethylsilane.<sup>[4]</sup>

Scheme 6.1 The reaction mechanism of a Hosomi-Sakurai reaction activated by the Lewis acid  $\text{TiCl}_4$ .

Early IR spectroscopy studies of the  $\text{AlCl}_3 \cdot \text{O}=\text{CCl}_2$  adduct showed a decrease of  $173 \text{ cm}^{-1}$  in the  $\text{C}=\text{O}$  stretching frequency upon adduct formation, which is indicative of an oxygen-bridged coordination complex as opposed to the formation of the ionic structure  $[\text{ClCO}][\text{AlCl}_4]$ .<sup>[5]</sup> The relatively low Lewis basicity of neutral, organic oxygen bases results in a low stability of the adduct, and, in the case of  $\text{AlCl}_3 \cdot \text{O}=\text{CCl}_2$ , full dissociation occurred under ambient conditions.<sup>[5,6]</sup> Only a few X-ray crystallography studies have been carried out on main-group Lewis acid-base adducts with carbonyl compounds.<sup>[7]</sup> One crystal structure shows the  $\text{BF}_3$ ·benzaldehyde adduct with a  $\text{B} \cdots \text{O}$  interaction of  $1.59 \text{ \AA}$  in an *E*-configuration (Figure 6.1).<sup>[3]</sup> Semi-empirical MNDO (Modified Neglect of Diatomic Overlap) calculations of the  $\text{BF}_3 \cdot \text{O}=\text{CHCH}_3$  adduct also showed the *E*-configuration to be more favourable over the *Z*-configuration by  $7.5 \text{ kJ/mol}$ .<sup>[3]</sup> A  $^{13}\text{C}$  NMR spectroscopy study

of Lewis acid-base adducts between  $\text{BF}_3$  and various aliphatic ketones, such as acetone and cyclopentanone, showed the  $^{13}\text{C}$  resonances of the  $\alpha$ -carbons to shift to higher frequencies by 24.3 and 26.2 ppm, respectively.<sup>[8]</sup> A crystallographic study of 1:1  $\text{AlCl}_3$ ·tetramethylurea showed the existence of an  $\text{Al}\cdots\text{O}$  interaction with an  $\text{Al}\cdots\text{O}$  distance of 1.78 Å and an  $\text{Al}\cdots\text{O}\cdots\text{C}$  angle of  $132.5^\circ$ .<sup>[9]</sup>

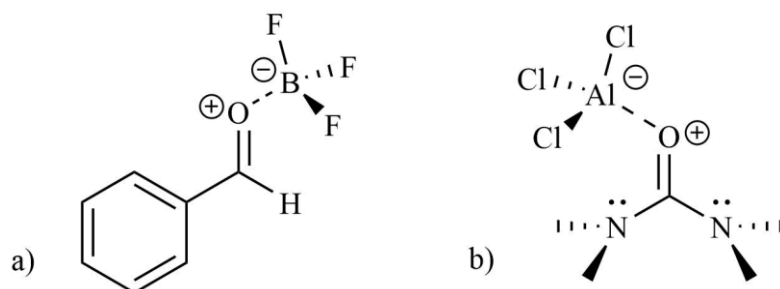

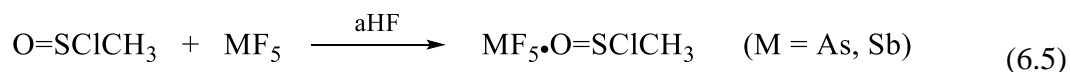

Figure 6.1 Structures of (a) the *E*-configuration of the adduct between  $\text{BF}_3$  and benzaldehyde and (b) the adduct between  $\text{AlCl}_3$  and tetramethylurea.

The 1:1 adducts of  $\text{O}=\text{CCl}_2$ ,  $\text{O}=\text{CClF}$ , and  $\text{O}=\text{CF}_2$  with the strong Lewis acids,  $\text{AsF}_5$  and  $\text{SbF}_5$ , were synthesized and also found to dissociate at ambient temperature.<sup>[6]</sup> Vibrational and multinuclear NMR spectroscopies were used to characterize these Lewis acid-base adducts at low temperatures. Upon adduct formation, the  $\nu(\text{CO})$  stretching frequencies significantly decreased by upwards of  $240\text{ cm}^{-1}$  ( $\text{O}=\text{CCl}_2$ ) and  $199\text{ cm}^{-1}$  ( $\text{O}=\text{CClF}$ ). Geometries were optimized in the gas-phase at the B3LYP/SBK+(d) level of theory and the calculated energies were used to determine the relative stability amongst the carbonyl halide adducts with  $\text{AsF}_5$  and  $\text{SbF}_5$ . The  $\text{SbF}_5\cdot\text{O}=\text{CCl}_2$  adduct was determined to be the most stable. Passmore and co-workers were able to synthesize the 1:1 adduct of  $\text{O}=\text{CF}_2$  with  $\text{AsF}_5$  and  $\text{SbF}_5$  in both the liquid and solid states.<sup>[10]</sup> Low-temperature Raman spectroscopy showed a decrease of 118 and  $136\text{ cm}^{-1}$  in the  $\text{C}=\text{O}$  stretching frequency upon

formation of the oxygen-bridged adducts  $\text{AsF}_5 \cdot \text{O}=\text{CF}_2$  and  $\text{SbF}_5 \cdot \text{O}=\text{CF}_2$ , respectively, compared to their respective free ketones. Dissociation occurred upon warming to RT, however, in all cases the reactions were found to be reversible.

Matrix-isolation studies have shown ketones, including acetone, cyclopentanone, and adamantanone, to form complexes with  $\text{SbF}_5$ . Vibrational spectroscopy, complimented with semi-empirical and *ab initio* calculations, showed decreases in the characteristic  $\text{C}=\text{O}$  stretching frequencies.<sup>[11]</sup> Adducts of dimethyl ether and dimethyl peroxide with  $\text{AsF}_5$  were synthesized in the solid state and characterized by Raman spectroscopy.<sup>[12]</sup> Only the stability of  $\text{AsF}_5 \cdot \text{CH}_3\text{OOCH}_3$  was reported and decomposition occurred at  $-30^\circ\text{C}$ .

A series of 1:1  $\text{S}=\text{O} \cdots \text{MF}_5$  ( $\text{M} = \text{As}, \text{Sb}$ ) coordination complexes have been studied by Raman and NMR spectroscopy including adducts of  $\text{SO}_2$ ,  $\text{SOF}_2$ , and  $\text{SO}_2\text{F}_2$ .<sup>[10]</sup> The  $\nu(\text{SO})/\nu_s(\text{SO})$  frequencies decreased by values ranging from  $26\text{ cm}^{-1}$  ( $\text{AsF}_5 \cdot \text{SO}_2\text{F}_2$ ) to  $141\text{ cm}^{-1}$  ( $\text{SbF}_5 \cdot \text{SOF}_2$ ). Minkwitz et al. synthesized the  $\text{MF}_5 \cdot \text{O}=\text{SClCH}_3$  ( $\text{M} = \text{As}, \text{Sb}$ ) adducts by reaction of  $\text{O}=\text{SClCH}_3$  with  $\text{MF}_5$  in aHF at  $-70^\circ\text{C}$  (Equation 6.5).<sup>[13]</sup> These compounds were found to be stable towards dissociation below  $-20^\circ\text{C}$  and were characterized by Raman and  $^1\text{H}$  and  $^{13}\text{C}$  NMR spectroscopy. This same study also reported the X-ray crystal structure of  $\text{SbCl}_5 \cdot \text{O}=\text{SClCH}_3$  which was obtained by reaction of  $\text{SbCl}_5$  with  $\text{O}=\text{SClCH}_3$ . Despite using a superacidic medium,  $\text{HF}/\text{MF}_5$ , protonation of the  $\text{S}=\text{O}$  bond was reportedly not observed.

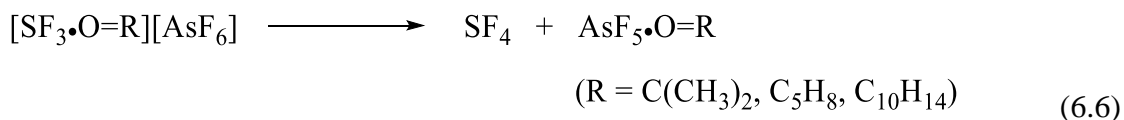

The interaction of strong Lewis acids, such as  $\text{AsF}_5$  and  $\text{SbF}_5$ , with weak Lewis bases, such as oxygen containing molecules, has been relatively unexplored. One of the first oxygen-base adducts to  $\text{AsF}_5$  to be synthesized was  $\text{AsF}_5 \cdot \text{O}(\text{CH}_3)_2$  and was

characterized by  $^1\text{H}$  and  $^{19}\text{F}$  NMR spectroscopy.<sup>[14]</sup> Two  $^{19}\text{F}$  resonances at  $-86$  (axial fluorine atom) and  $-61$  ppm (equatorial fluorine atoms on As) were observed as a result of the adopted octahedral geometry about As upon formation of the  $\text{AsF}_5 \cdot \text{O}(\text{CH}_3)_2$  adduct. Due to the quadrupole relaxation of the arsenic nucleus, the fluorine resonance lines were broadened to the point where no fluorine-fluorine spin coupling was observed. However, the quadrupolar relaxation of  $^{75}\text{As}$  was not rapid enough to cause complete self-decoupling that would result in sharp  $^{19}\text{F}$  signals. Since  $\text{N}(\text{CH}_3)_3$  is a stronger base than  $\text{O}(\text{CH}_3)_2$ , the electric field gradient about  $^{75}\text{As}$  in  $\text{AsF}_5 \cdot \text{N}(\text{CH}_3)_3$  is smaller and quadrupolar relaxation is slower. As a consequence, equal-intensity quartet splitting of the resonances at  $-74.8$  and  $-67.4$  ppm were observed in the  $^{19}\text{F}$  NMR spectrum arising from  $^1J(^{75}\text{As}-^{19}\text{F})$  coupling of 840 and 1048 Hz, respectively. Doublet ( $-67.4$  ppm) and quintet ( $-74.8$  ppm) splittings arising from the  $^2J(^{19}\text{F}-^{19}\text{F})$  coupling of 120 Hz were also discerned.

## 6.2 Results and Discussion

### 6.2.1 Synthesis and Properties of Lewis Acid-Base Adducts of Acetone, Cyclopentanone, and 2-Adamantanone with $\text{AsF}_5$

During the studies of Lewis acid-base interactions between  $[\text{SF}_3][\text{AsF}_6]$  and ketones (see Chapter 4), one of the decomposition products observed in the  $^{19}\text{F}$  NMR spectra upon warming above  $-40$  °C was a 1:1 adduct between the neutral ketone and  $\text{AsF}_5$  (Equation 6.6).

As before, the ketones chosen for this study were acetone, an aliphatic compound, cyclopentanone, a monocyclic compound, and 2-adamantanone, a polycyclic compound (Figure 6.2).

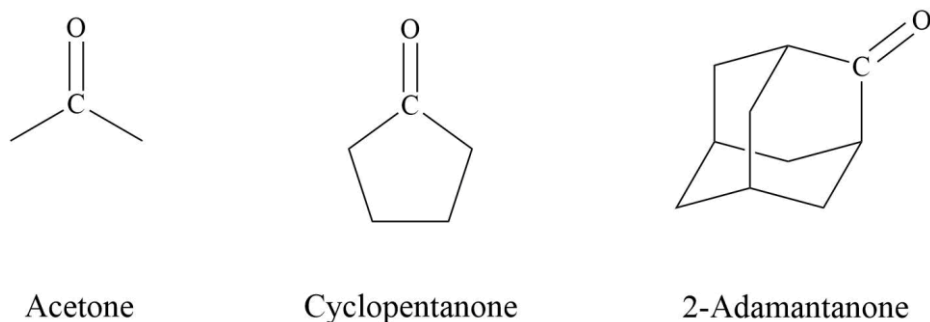

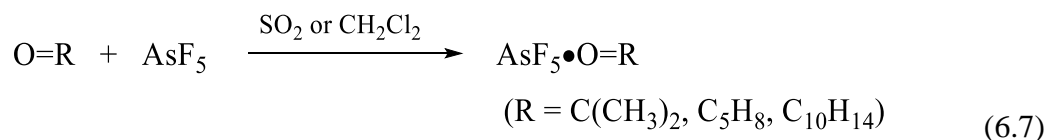

Figure 6.2 Structures of the ketones used to form adducts with AsF<sub>5</sub>.

Targeted reactions were performed where a known amount of acetone, cyclopentanone, or 2-adamantanone was dissolved in SO<sub>2</sub> at RT. A stoichiometric amount of AsF<sub>5</sub> was added to the solution and the reactions were allowed to proceed at −78 °C. Dichloromethane was also a suitable solvent for reactions with 2-adamantanone and cyclopentanone. Using CH<sub>2</sub>Cl<sub>2</sub> resulted in instantaneous reactions forming an insoluble fine, white powder, while using SO<sub>2</sub> resulted in a clear, colourless solution. Removing the solvent at −78 °C yielded white powders identified by LT Raman spectroscopy as the 1:1 adducts of AsF<sub>5</sub>·O=R (Equation 6.7). Crystal growth of these adducts from SO<sub>2</sub> and CH<sub>2</sub>Cl<sub>2</sub> was unsuccessful.

Upon warming the solid AsF<sub>5</sub>·O=C(CH<sub>3</sub>)<sub>2</sub> adduct to RT, the sample quickly decomposed into a dark yellow powder unidentifiable by Raman spectroscopy due to

significant fluorescence. The  $\text{AsF}_5 \cdot \text{O}=\text{C}_5\text{H}_8$  and  $\text{AsF}_5 \cdot \text{O}=\text{C}_{10}\text{H}_{14}$  adducts were stable at RT for roughly 1 h before the samples began turning light brown in colour. While LT Raman spectroscopy showed fluorescence in the baseline, some Raman bands attributable to the adducts were still observed. After two days the  $\text{AsF}_5 \cdot \text{O}=\text{C}_5\text{H}_8$  and  $\text{AsF}_5 \cdot \text{O}=\text{C}_{10}\text{H}_{14}$  adducts were of grey colour and unidentifiable by Raman spectroscopy due to a large fluorescence.

These adducts were also characterized in solution using  $^1\text{H}$  and  $^{19}\text{F}$  NMR spectroscopy at  $-70\text{ }^\circ\text{C}$  in  $\text{SO}_2$  and were found to be stable at RT in solution, even after 40 min. A colour change was observed for the  $\text{AsF}_5 \cdot \text{O}=\text{C}(\text{CH}_3)_2$  adduct in  $\text{SO}_2$  to yellow, most likely as a result of some acetone undergoing redox chemistry due to the presence of excess  $\text{AsF}_5$  in solution. The  $\text{AsF}_5 \cdot \text{O}=\text{C}_5\text{H}_8$ , and  $\text{AsF}_5 \cdot \text{O}=\text{C}_{10}\text{H}_{14}$  compounds were stable and did not show any colour change upon warming to RT.

### 6.2.2 Raman Spectroscopy

The Raman spectra of  $\text{AsF}_5 \cdot \text{O}=\text{C}(\text{CH}_3)_2$ ,  $\text{AsF}_5 \cdot \text{O}=\text{C}_5\text{H}_8$ , and  $\text{AsF}_5 \cdot \text{O}=\text{C}_{10}\text{H}_{14}$  were recorded at  $-100\text{ }^\circ\text{C}$  and are depicted in Figures 6.3–6.5. Vibrational frequencies of the geometry-optimized compounds were calculated and used to aid in the assignments of the Raman bands. The complete list of experimental and calculated vibrational bands can be found in Appendix Tables A.3.4–A.3.6.

Table 6.1 Observed and Calculated  $\nu(\text{CO})$  Frequencies ( $\text{cm}^{-1}$ ) for  $\text{AsF}_5 \cdot \text{O}=\text{C}(\text{CH}_3)_2$ ,  $\text{AsF}_5 \cdot \text{O}=\text{C}_5\text{H}_8$ , and  $\text{AsF}_5 \cdot \text{O}=\text{C}_{10}\text{H}_{14}$ , as well as their Free Ketones.

The interaction of the Lewis acid, AsF<sub>5</sub>, with each ketone resulted in changes of vibrational bands associated with the ketones in the Raman spectra, most dramatically for the characteristic  $\nu(\text{CO})$  frequency. A comparison of the  $\nu(\text{CO})$  frequencies is found in Table 6.1. Formation of the As---O dative bonds in the AsF<sub>5</sub>·O=R (R = C(CH<sub>3</sub>)<sub>2</sub>, C<sub>5</sub>H<sub>8</sub>, C<sub>10</sub>H<sub>14</sub>) adducts or the protonation of ketones (see Chapter 5) both result in a significant weakening of the C=O bond as reflected by a decrease in the  $\nu(\text{CO})$  stretch. Forming the AsF<sub>5</sub>·O=C(CH<sub>3</sub>)<sub>2</sub> adduct caused a decrease of 117 cm<sup>-1</sup> in the C=O stretching frequency compared to neat acetone. The AsF<sub>5</sub>·O=C<sub>5</sub>H<sub>8</sub> and AsF<sub>5</sub>·O=C<sub>10</sub>H<sub>14</sub> compounds showed decreases of 123 and 151 cm<sup>-1</sup> relative to their parent ketones, respectively. A previous matrix-isolation study of the complimentary SbF<sub>5</sub> adducts, SbF<sub>5</sub>·O=C(CH<sub>3</sub>)<sub>2</sub> ( $\Delta\nu$  = 110 cm<sup>-1</sup>), SbF<sub>5</sub>·O=C<sub>5</sub>H<sub>8</sub> ( $\Delta\nu$  = 125 cm<sup>-1</sup>), and SbF<sub>5</sub>·O=C<sub>10</sub>H<sub>14</sub> ( $\Delta\nu$  = 165 cm<sup>-1</sup>), used vibrational spectroscopy to show similar decreases in the C=O stretching frequencies. These changes in frequencies are also comparable to salts of the monoprotonated ketones [HO=C(CH<sub>3</sub>)<sub>2</sub>]<sup>+</sup> ( $\Delta\nu$  = 116 cm<sup>-1</sup>), [HO=C<sub>5</sub>H<sub>8</sub>]<sup>+</sup> ( $\Delta\nu$  = 122 cm<sup>-1</sup>), and [HO=C<sub>10</sub>H<sub>14</sub>]<sup>+</sup> ( $\Delta\nu$  = 155 cm<sup>-1</sup>).<sup>[15]</sup> Calculated frequencies of the geometry optimized gas-phase structures predicted slightly smaller decreases in C=O frequencies (AsF<sub>5</sub>·O=C(CH<sub>3</sub>)<sub>2</sub> 99 cm<sup>-1</sup>; AsF<sub>5</sub>·O=C<sub>5</sub>H<sub>8</sub> 100 cm<sup>-1</sup>; and AsF<sub>5</sub>·O=C<sub>10</sub>H<sub>14</sub> 111 cm<sup>-1</sup>). The ring breathing modes of cyclopentanone, 811 cm<sup>-1</sup>, and 2-adamantanone, 717 cm<sup>-1</sup>, increased to 841 and 745 cm<sup>-1</sup>, respectively, for the synthesized AsF<sub>5</sub>·O=C<sub>5</sub>H<sub>8</sub> and AsF<sub>5</sub>·O=C<sub>10</sub>H<sub>14</sub> compounds. The  $\nu_s(\text{CCC})$  stretching frequency of AsF<sub>5</sub>·O=C(CH<sub>3</sub>)<sub>2</sub> (838 cm<sup>-1</sup>) is also increased relative to acetone (788 cm<sup>-1</sup>). Comparable to similar trends for the monoprotonated ketones, the interaction of AsF<sub>5</sub> with the carbonyl group causes a strengthening of the *cis* and *trans* C–C bonds.

The characteristic As–F stretches of adducted AsF<sub>5</sub> appear as intense bands in the Raman spectra. For AsF<sub>5</sub>·O=C(CH<sub>3</sub>)<sub>2</sub>, the  $\nu_s(\text{AsF}_{4,\text{eq}})$  stretching frequency at 660 cm<sup>−1</sup> was the most intense Raman band. The second most intense band at 710 cm<sup>−1</sup> was assigned to the  $\nu(\text{AsF}_{\text{ax}})$  stretching frequency. The frequencies of these bands are rather invariant between the adducts of the three ketones: AsF<sub>5</sub>·O=C<sub>5</sub>H<sub>8</sub> ( $\nu(\text{AsF}_{\text{ax}})$  711;  $\nu_s(\text{AsF}_{4,\text{eq}})$  659 cm<sup>−1</sup>) and AsF<sub>5</sub>·O=C<sub>10</sub>H<sub>14</sub> ( $\nu(\text{AsF}_{\text{ax}})$  704;  $\nu_s(\text{AsF}_{4,\text{eq}})$  661 cm<sup>−1</sup>). The calculated  $\nu(\text{AsF}_{\text{ax}})$  stretches for the adducts were slightly overestimated (by upwards of 25 cm<sup>−1</sup>) and  $\nu_s(\text{AsF}_{4,\text{eq}})$  stretches were underestimated (by upwards of 9 cm<sup>−1</sup>) when compared to the experimental values.

### 6.2.3 NMR Spectroscopy

The <sup>19</sup>F and <sup>1</sup>H resonances of AsF<sub>5</sub>·O=C(CH<sub>3</sub>)<sub>2</sub>, AsF<sub>5</sub>·O=C<sub>5</sub>H<sub>8</sub>, and AsF<sub>5</sub>·O=C<sub>10</sub>H<sub>14</sub> are listed in Table 6.2 and the <sup>19</sup>F NMR spectra are depicted in Figure 6.6. The <sup>19</sup>F and <sup>1</sup>H NMR spectra were collected at −70 °C in liquid SO<sub>2</sub>.

The <sup>19</sup>F NMR spectra of AsF<sub>5</sub>·O=C(CH<sub>3</sub>)<sub>2</sub>, AsF<sub>5</sub>·O=C<sub>5</sub>H<sub>8</sub>, and AsF<sub>5</sub>·O=C<sub>10</sub>H<sub>14</sub> adducts contained two signals: doublets arising from the equatorial fluorine environments of AsF<sub>5</sub> at −48.37 ( $\Delta\nu_{1/2}$  = 90 Hz), −50.87 ( $\Delta\nu_{1/2}$  = 53 Hz), and −46.72 ( $\Delta\nu_{1/2}$  = 61 Hz) ppm; and quintets arising from the axial fluorine atoms of AsF<sub>5</sub> at −73.28 ( $\Delta\nu_{1/2}$  = 105 Hz), −73.27 ( $\Delta\nu_{1/2}$  = 62 Hz), and −71.59 ( $\Delta\nu_{1/2}$  = 49 Hz) ppm, respectively.

Table 6.2  $^{19}\text{F}$  and  $^1\text{H}$  NMR chemical shifts ( $\delta$ ) for  $\text{AsF}_5 \cdot \text{O}=\text{C}(\text{CH}_3)_2$ ,  $\text{AsF}_5 \cdot \text{O}=\text{C}_5\text{H}_8$ , and  $\text{AsF}_5 \cdot \text{O}=\text{C}_{10}\text{H}_{14}$ , as well as their neutral ketones, in  $\text{SO}_2$  at  $-70^\circ\text{C}$ .

<sup>a</sup> Abbreviations: (s) singlet; (d) doublet; (qn) quintet; (eq) equatorial; (ax) axial.

<sup>b</sup> Obtained by spectral simulation using Mestre Nova

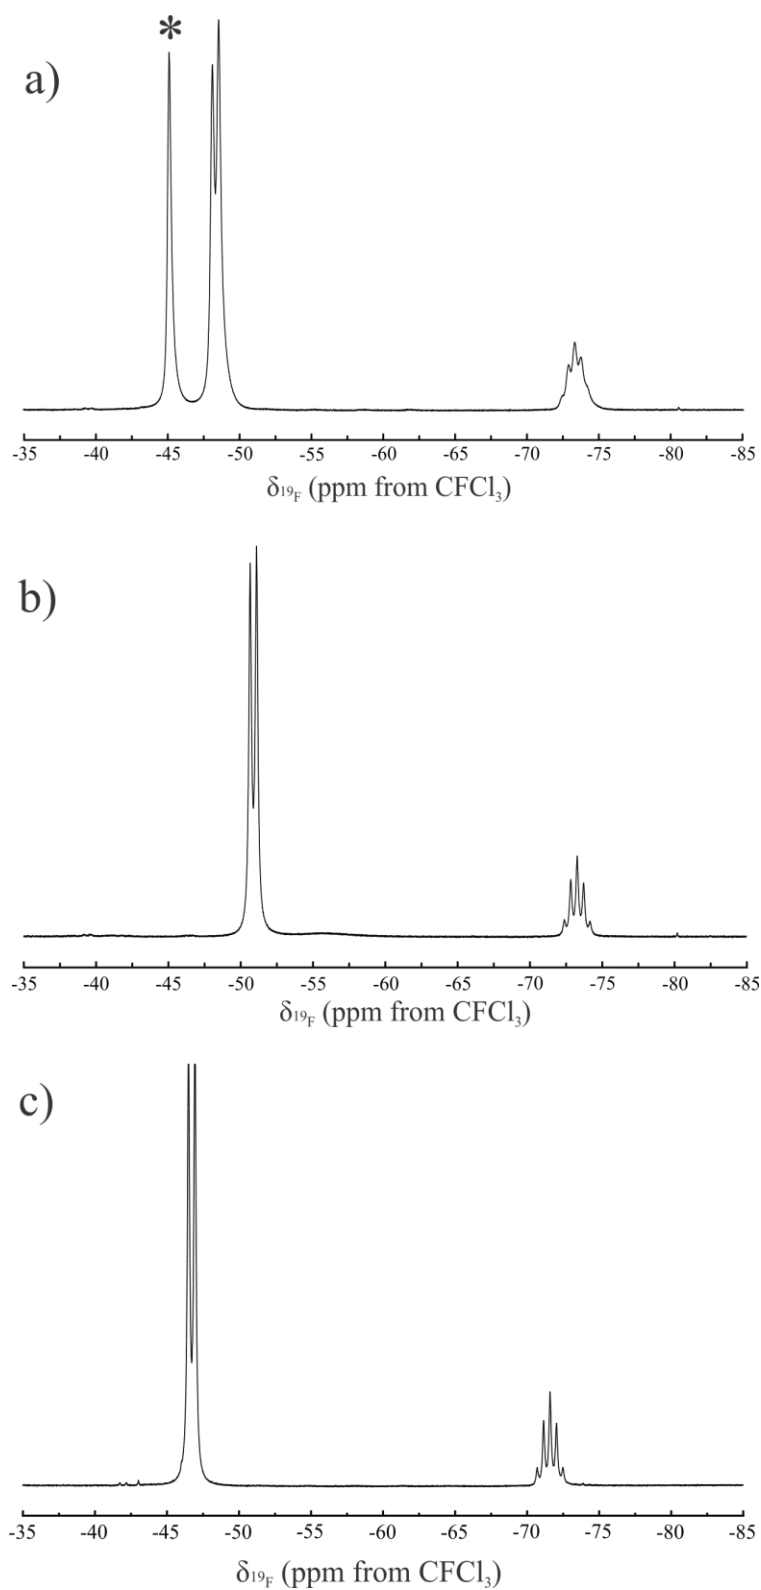

Figure 6.6  $^{19}\text{F}$  NMR spectrum of (a)  $\text{AsF}_5 \cdot \text{O}=\text{C}(\text{CH}_3)_2$ , (b)  $\text{AsF}_5 \cdot \text{O}=\text{C}_5\text{H}_8$ , and (c)  $\text{AsF}_5 \cdot \text{O}=\text{C}_{10}\text{H}_{14}$  (c) adducts in liquid  $\text{SO}_2$  at  $-70^\circ\text{C}$ . Externally referenced to  $\text{CFCl}_3$ . The symbol (\*) denotes the  $\text{AsF}_5 \cdot \text{SO}_2$  signal.

Upon accepting an electron lone pair from the ketone, the trigonal bipyramidal geometry of free  $\text{AsF}_5$  changes and adopts a pseudo octahedral geometry with the  $\text{C}=\text{O}---\text{As}$  moiety in the axial position. At  $-70\text{ }^\circ\text{C}$  the exchange between the axial and equatorial ligands is slow enough to observe the two distinct environments on an NMR timescale. The scalar  $^2J(^{19}\text{F}-^{19}\text{F})$  coupling of 124 or 125 Hz between the equatorial and axial fluorine atoms for  $\text{AsF}_5\cdot\text{O}=\text{R}$  is a result of this adopted pseudo octahedral geometry.

When  $\text{AsF}_5$  was added to  $\text{SO}_2$  in the presence of no ketone, even at  $-70\text{ }^\circ\text{C}$ , only a singlet at  $-44.71\text{ ppm}$  ( $\Delta\nu_{1/2} = 88\text{ Hz}$ ) corresponding to the  $\text{AsF}_5\cdot\text{SO}_2$  adduct was observed in the  $^{19}\text{F}$  NMR spectrum. In the  $^{19}\text{F}$  NMR spectrum of  $\text{AsF}_5\cdot\text{O}=\text{C}(\text{CH}_3)_2$ , the resonance at  $-45.18\text{ ppm}$  ( $\Delta\nu_{1/2} = 86\text{ Hz}$ ) (Figure 6.6) was attributed to the  $\text{AsF}_5\cdot\text{SO}_2$  adduct formed due to a slight excess of  $\text{AsF}_5$  in solution. This adduct was previously characterized by Raman spectroscopy and  $^{19}\text{F}$  NMR spectroscopy.<sup>[10,16]</sup> Unlike  $\text{AsF}_5\cdot\text{SO}_2$ , the relatively strong  $\text{As}---\text{O}$  interactions in the  $\text{AsF}_5\cdot\text{O}=\text{R}$  adducts result in slow exchange between the fluorine environments and observation of scalar  $^2J(^{19}\text{F}-^{19}\text{F})$  coupling. The electric field gradient about  $^{75}\text{As}$  in these adducts causes rapid quadrupolar relaxation of the  $^{75}\text{As}$  ( $I = 3/2$ , 100%) nucleus with no  $^1J(^{75}\text{As}-^{19}\text{F})$  coupling being observed. The  $^1\text{H}$  resonances of the non-adducted ketones, acetone, cyclopentanone, and 2-adamantanone, are all shifted to higher frequencies upon addition of  $\text{AsF}_5$  at  $-70\text{ }^\circ\text{C}$  in  $\text{SO}_2$  (Table 6.2). The  $\text{AsF}_5\cdot\text{O}=\text{R}$  adducts show increasing peak width at half height values ( $\Delta\nu_{1/2}$ ) from  $\text{O}=\text{C}_{10}\text{H}_{14} < \text{O}=\text{C}_5\text{H}_8 < \text{O}=\text{C}(\text{CH}_3)_2$  (Table 6.2). The donor strength of acetone ( $76.03\pm0.21\text{ kJ/mol}$ ) and cyclopentanone ( $77.44\pm0.45\text{ kJ/mol}$ ), measured by their affinity to  $\text{BF}_3$ , are too similar to account for the difference in  $\Delta\nu_{1/2}$  values.<sup>[17]</sup> The calculated  $\text{As}---\text{O}$  distances in the gas-phase adducts are also similar and, therefore, will not account for the broadening observed

in the  $^{19}\text{F}$  NMR spectrum of  $\text{AsF}_5 \cdot \text{O}=\text{C}(\text{CH}_3)_2$ . The slight excess of  $\text{AsF}_5$  in solution, as noted from the  $\text{AsF}_5 \cdot \text{SO}_2$  signal in the  $^{19}\text{F}$  NMR spectrum of  $\text{AsF}_5 \cdot \text{O}=\text{C}(\text{CH}_3)_2$  (see Figure 6.6a), could be the cause of the broadening of signals as a result of exchange of  $\text{AsF}_5$  between the acetone and  $\text{SO}_2$ . After warming the reaction to RT for 40 min, the  $^{19}\text{F}$  resonance at  $-45.18$  ppm was no longer present and the doublet ( $-48.3$  ppm) and quintet ( $-73.34$  ppm) from  $\text{AsF}_5 \cdot \text{O}=\text{C}(\text{CH}_3)_2$  became sharper (Figure 6.7). As well, some  $[\text{AsF}_6]^-$  was formed as shown from the equal intensity quartet at  $-56.8$  with a  $^1J(^{19}\text{F}-^{75}\text{As})$  coupling of 926 Hz. Although the source of the  $\text{F}^-$  that produces  $[\text{AsF}_6]^-$  is not conclusively known, it may be formed by reaction of  $\text{HF}$ , produced by hydrolysis from trace amounts of moisture through the FEP reactor after having been left at RT for 40 min, with  $\text{AsF}_5$  to produce  $[\text{H}_2\text{F}][\text{AsF}_6]$  in small quantities.

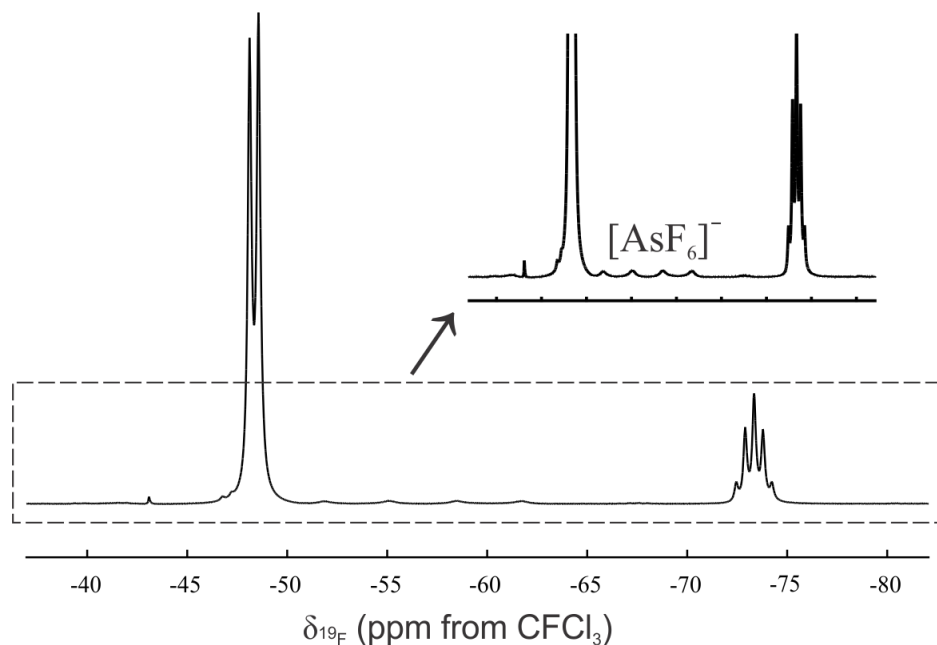

Figure 6.7  $^{19}\text{F}$  NMR spectrum of  $\text{AsF}_5 \cdot \text{O}=\text{C}(\text{CH}_3)_2$  after warming to RT for 40 min. Externally referenced to  $\text{CFC1}_3$ .

## 6.2.4 Computational Results

Density functional theory (DFT) calculations were carried out on the  $\text{AsF}_5 \cdot \text{O}=\text{R}$  adducts ( $\text{R} = \text{C}(\text{CH}_3)_2$ ,  $\text{C}_5\text{H}_8$ ,  $\text{C}_{10}\text{H}_{14}$ ) along with their parent ketones. The B3LYP functional was chosen along with the aug-cc-pVTZ (used for  $\text{AsF}_5 \cdot \text{O}=\text{C}(\text{CH}_3)_2$ ) and cc-pVTZ (used for  $\text{AsF}_5 \cdot \text{O}=\text{C}_5\text{H}_8$  and  $\text{AsF}_5 \cdot \text{O}=\text{C}_{10}\text{H}_{14}$ ) basis sets as it consistently provides reliable structural information (see Chapter 2, Section 2.11 for method validation). The gas-phase geometries of the compounds  $\text{AsF}_5 \cdot \text{O}=\text{C}(\text{CH}_3)_2$ ,  $\text{AsF}_5 \cdot \text{O}=\text{C}_5\text{H}_8$ , and  $\text{AsF}_5 \cdot \text{O}=\text{C}_{10}\text{H}_{14}$ , as well as the respective free ketones, were optimized and the geometric parameters can be found in Appendix Tables A.3.1–A.3.3 (Figure 6.8). A summary of selected geometric parameters is given in Table 6.3. These adducts adopt a pseudo octahedral geometry around the As center and the As---O distances range between 2.044 ( $\text{AsF}_5 \cdot \text{O}=\text{C}_{10}\text{H}_{14}$ ) and 2.065 Å ( $\text{AsF}_5 \cdot \text{O}=\text{C}(\text{CH}_3)_2$ ). The ketones form weak bonds with  $\text{AsF}_5$  at As–O–C angles of 133.06, 130.27, and 132.56° for  $\text{AsF}_5 \cdot \text{O}=\text{C}(\text{CH}_3)_2$ ,  $\text{AsF}_5 \cdot \text{O}=\text{C}_5\text{H}_8$ , and  $\text{AsF}_5 \cdot \text{O}=\text{C}_{10}\text{H}_{14}$ , respectively. These angles are larger than the reported B–O–C angle of 118.7(3)° in the crystal structure of the  $\text{BF}_3 \cdot \text{benzaldehyde}$  adduct,<sup>[3]</sup> which is likely a result of the  $\text{AsF}_5$  moiety being larger than  $\text{BF}_3$  and providing more steric hinderance resulting in a larger angle. The As–O–C–C dihedral angles for each adduct deviate by no more than 1.89° ( $\text{AsF}_5 \cdot \text{O}=\text{C}_5\text{H}_8$ ) from 0° resulting in the As–O–CC<sub>2</sub> moiety being essentially planar. These geometries were used to calculate the vibrational frequencies along with IR and Raman intensities and generally showed excellent agreement with the experimental values (*vide supra*), as listed in Appendix A.3.4–A.3.6.

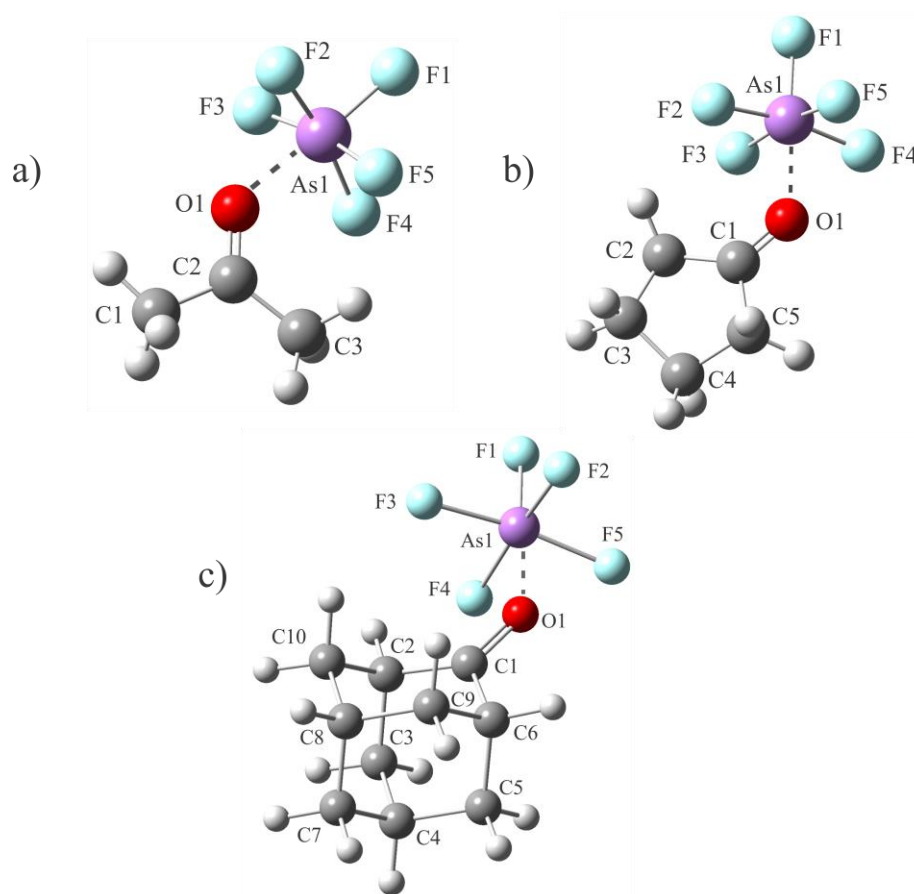

Figure 6.8 Optimized gas-phase geometries of a)  $\text{AsF}_5 \cdot \text{O}=\text{C}(\text{CH}_3)_2$ , b)  $\text{AsF}_5 \cdot \text{O}=\text{C}_5\text{H}_8$ , and c)  $\text{AsF}_5 \cdot \text{O}=\text{C}_{10}\text{H}_{14}$ .

Natural bond order (NBO) analyses were carried out to investigate the bonding in these  $\text{AsF}_5 \cdot \text{O}=\text{R}$  compounds (Appendix Tables A.3.7–A.3.9). A summary of the NBO analyses is found in Table 6.4.

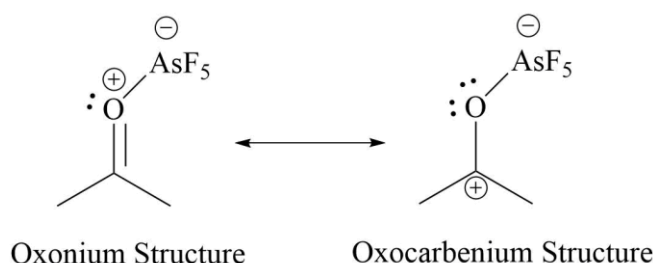

Table 6.4 Selected NPA Charges, Valences and Wiberg Bond Indices of the  $\text{AsF}_5 \cdot \text{O}=\text{R}$  ( $\text{R} = \text{C}(\text{CH}_3)_2$ ,  $\text{C}_5\text{H}_8$ , and  $\text{C}_{10}\text{H}_{14}$ ) Compounds and their Respective Free Ketones.

	NPA Charges (Valences <sup>[a]</sup> )	NPA Charges (Valences <sup>[a]</sup> )	Wiberg Bond Indices	
	O	C	CO	As---O
$\text{O}=\text{C}(\text{CH}_3)_2$	−0.55 (2.04)	0.59 (3.87)	1.83	
$\text{AsF}_5 \cdot \text{O}=\text{C}(\text{CH}_3)_2$	−0.59 (2.14)	0.69 (3.78)	1.59	0.29
$\text{O}=\text{C}_5\text{H}_8$	−0.54 (2.06)	0.60 (3.87)	1.84	
$\text{AsF}_5 \cdot \text{O}=\text{C}_5\text{H}_8$	−0.59 (2.15)	0.71 (3.77)	1.60	0.30
$\text{O}=\text{C}_{10}\text{H}_{14}$	−0.56 (2.04)	0.61 (3.87)	1.83	
$\text{AsF}_5 \cdot \text{O}=\text{C}_{10}\text{H}_{14}$	−0.61 (2.14)	0.73 (3.76)	1.57	0.31

<sup>[a]</sup> Sum of the Wiberg Bond Indices per atom.

For each of the  $\text{AsF}_5 \cdot \text{O}=\text{R}$  adducts, the Natural Population Analysis (NPA) charge on the carbonyl carbon increased by between 0.10 and 0.12. The negative charge on oxygen increased by 0.04, for  $\text{AsF}_5 \cdot \text{O}=\text{C}(\text{CH}_3)_2$ , and 0.05, for  $\text{AsF}_5 \cdot \text{O}=\text{C}_5\text{H}_8$ , and  $\text{AsF}_5 \cdot \text{O}=\text{C}_{10}\text{H}_{14}$ . This is comparable to the monoprotonated ketones  $[\text{HO}=\text{R}]^+$  ( $\text{R} = \text{C}_{10}\text{H}_{14}$ ,  $\text{C}_5\text{H}_8$ , or  $\text{C}(\text{CH}_3)_2$ ) studied where the charge on carbon increased by between 0.13 and 0.14.<sup>[15]</sup> However, when looking at the calculated C=O Wiberg bond index (WBI), the  $\text{AsF}_5 \cdot \text{O}=\text{R}$  adducts did not show as great of a decrease in C=O bond order compared to the monoprotonated ketones. A decrease between 0.24 and 0.26 was calculated for  $\text{AsF}_5 \cdot \text{O}=\text{R}$ , whereas a decrease between 0.44 and 0.48 was calculated for the  $[\text{HO}=\text{R}]^+$  cations, all relative to the free ketones. Comparable to the  $[\text{HO}=\text{R}]^+$  cations, the oxonium structure is the dominant resonance over the carbenium structure in the  $\text{AsF}_5 \cdot \text{O}=\text{R}$  adducts (Scheme 6.2). The C=O bond in  $[\text{HO}=\text{R}]^+$  cations is more polarized than in  $\text{AsF}_5 \cdot \text{O}=\text{R}$  adducts,

which is paralleled by the C=O bond in the  $[\text{HO}=\text{R}]^+$  cations containing less double-bond character than the  $\text{AsF}_5 \cdot \text{O}=\text{R}$  adducts, as shown by the lower bond index. Addition of the acid, whether it is  $\text{AsF}_5$  or  $[\text{H}]^+$ , is responsible for the increased positive charge on the carbon of the carbonyl and decreased C=O bond order.

Scheme 6.2 Resonance structures for  $\text{AsF}_5 \cdot \text{O}=\text{C}(\text{CH}_3)_2$ .

The As---O bond index in the adducts range from 0.29 to 0.31. The bond order for the As---O bonds is approximately half of that of the As-F bonds in the adducts (WBI = 0.56 to 0.62). For the protonated ketones, the strong polarization of the C=O bond by protonation can be explained by the much higher O-H bond order (0.70) compared to that of the As---O bond.

The molecular orbital energies were calculated for the  $\text{AsF}_5 \cdot \text{O}=\text{R}$  compounds (see Appendix Figures A.3.1–A.3.6). Using  $\text{AsF}_5 \cdot \text{O}=\text{C}(\text{CH}_3)_2$  as a representative example, Figure 6.9 shows the altered shape and energies of the HOMO and LUMO upon addition of  $\text{AsF}_5$ . A dramatic decrease in energy by 771 kJ/mol is observed for the HOMO, and 241 kJ/mol for the LUMO upon formation of  $\text{AsF}_5 \cdot \text{O}=\text{C}(\text{CH}_3)_2$ .

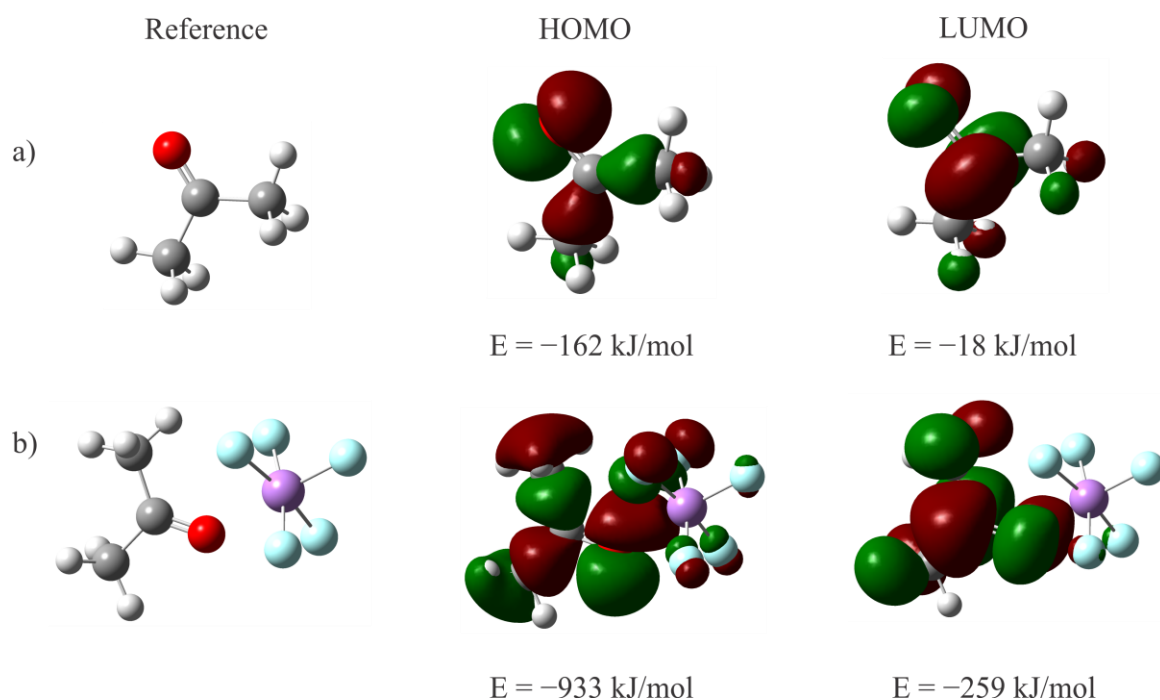

Figure 6.9 Molecular orbitals of a) acetone and b)  $\text{AsF}_5 \cdot \text{O}=\text{C}(\text{CH}_3)_2$ . From left to right are the reference molecules, HOMO diagrams, LUMO diagrams.

The formation of the  $\text{C}=\text{O} \cdots \text{As}$  moiety dramatically lowers the LUMO of the ketone creating a much more reactive species towards nucleophilic attack compared to the free ketone. The substantial decrease in energy of the HOMO significantly reduces the reactivity towards electrophilic attack. The HOMO also contains some  $\pi$  orbital contribution from the fluorine atoms of  $\text{AsF}_5$  which might contribute to the considerable lowering in energy. These findings are consistent with previous calculations for the  $[\text{HO}=\text{R}]^+$  cations. A summary of the HOMO and LUMO energies for the  $\text{AsF}_5 \cdot \text{O}=\text{R}$  adducts and  $[\text{HO}=\text{R}]^+$  cations is shown in Table 6.5. The LUMO energy of  $\text{AsF}_5 \cdot \text{O}=\text{C}(\text{CH}_3)_2$  ( $-259 \text{ kJ/mol}$ ) is significantly lower than that of  $[\text{HO}=\text{C}(\text{CH}_3)_2]^+$  ( $-189 \text{ kJ/mol}$ ) and will be more prone to nucleophilic attack. This may account for one of the reasons Lewis acids are used over  $[\text{H}]^+$  to activate specific organic reactions, such as the Diels-Alder reaction. A previous study

investigating the change in energy of the HOMO and LUMO of  $\text{BF}_3 \cdot \text{OCHCH}_3$  only showed a decrease of 80 kJ/mol in the LUMO and 173 kJ/mol in the HOMO.<sup>[3]</sup> This can be attributed to the stronger Lewis acidity of  $\text{AsF}_5$  compared to  $\text{BF}_3$ , whereby the  $\text{C}=\text{O} \cdots \text{As}$  moiety more heavily influences the reactivity of the ketone.

Table 6.5 Calculated Energies (kJ/mol) of the HOMO and LUMO for the  $\text{AsF}_5 \cdot \text{O}=\text{R}$  Adducts and the Protonated Ketones  $[\text{H}(\text{O}=\text{R})_x]^+$  ( $x = 1$  or  $2$ ;  $\text{R} = \text{C}(\text{CH}_3)_2$ ,  $\text{C}_5\text{H}_8$ ,  $\text{C}_{10}\text{H}_{14}$ ).

Compound	HOMO Energy	LUMO Energy
$\text{O}=\text{C}_{10}\text{H}_{14}$	-151	-13
$[\text{HO}=\text{C}_{10}\text{H}_{14}]^+$	-286	-163
$\text{AsF}_5 \cdot \text{O}=\text{C}_{10}\text{H}_{14}$	-837	-229
$\text{O}=\text{C}_5\text{H}_8$	-157	-20
$[\text{HO}=\text{C}_5\text{H}_8]^+$	-323	-182
$\text{AsF}_5 \cdot \text{O}=\text{C}_5\text{H}_8$	-890	-256
$\text{O}=\text{C}(\text{CH}_3)_2$	-162	-18
$[\text{HO}=\text{C}(\text{CH}_3)_2]^+$	-376	-189
$[\text{H}(\text{O}=\text{C}(\text{CH}_3)_2)_2]^+$	-1203	-596
$\text{AsF}_5 \cdot \text{O}=\text{C}(\text{CH}_3)_2$	-933	-259

### 6.3 Summary and Conclusions

For the first time, Lewis acid-base adducts of aliphatic and alicyclic ketones with  $\text{AsF}_5$  were synthesized and characterized by Raman,  $^1\text{H}$ , and  $^{19}\text{F}$  NMR spectroscopies. These  $\text{AsF}_5 \cdot \text{O}=\text{R}$  adducts ( $\text{R} = \text{C}(\text{CH}_3)_2$ ,  $\text{C}_5\text{H}_8$ ,  $\text{C}_{10}\text{H}_{14}$ ) adducts were isolated as white powders and found to decompose upon warming to RT. Raman spectroscopy showed characteristic bands of the ketones that are shifted upon addition of  $\text{AsF}_5$  and subsequent adduct formation. Specifically, the  $\text{C}=\text{O}$  stretching frequency dramatically decreased by between  $107\text{--}151\text{ cm}^{-1}$  and  $\nu_s(\text{CCC})$  stretches and ring breathing modes of the ketones increased to higher frequencies. The  $^{19}\text{F}$  NMR spectra of these compounds showed they had developed pseudo octahedral geometries about the  $^{75}\text{As}$  metal center. While no

$^1J(^{75}\text{As}-^{19}\text{F})$  coupling could be distinguished, the  $^2J(^{19}\text{F}-^{19}\text{F})$  coupling between the axial and equatorial fluorine environments of  $\text{AsF}_5$  was observed.

NBO analyses of these  $\text{AsF}_5 \cdot \text{O}=\text{R}$  adducts showed an increase in the charge of the carbon of the carbonyl group, as well as, a decrease in the  $\text{C}=\text{O}$  bond order due to the strong Lewis acid,  $\text{AsF}_5$ , withdrawing electron density from the  $\text{C}=\text{O}$  group. Decreases in the HOMO and LUMO energies also confirmed the activation and increased reactivity of the ketones in Lewis-acid catalyzed organic reactions. These results are comparable to the oxonium  $[\text{HO}=\text{R}]^+$  cations ( $\text{R} = \text{C}(\text{CH}_3)_2, \text{C}_5\text{H}_8, \text{C}_{10}\text{H}_{14}$ ) typically observed as intermediates in acid-catalyzed organic reactions. DFT calculations showed the  $\text{C}=\text{O}$  bond of  $[\text{HO}=\text{R}]^+$  cations to contain more single-bond character than the  $\text{AsF}_5 \cdot \text{O}=\text{R}$  adducts, as indicated by larger decreases in the  $\text{C}=\text{O}$  bond order. While the  $\text{C}=\text{O}$  bond is less polarized by  $\text{AsF}_5$  compared to  $\text{HF}$ , the LUMO of the  $\text{AsF}_5 \cdot \text{O}=\text{R}$  adduct is lower in energy than the  $[\text{HO}=\text{R}]^+$  cation confirming why the reactivity of carbonyl compounds are enhanced by Lewis acids and sometimes favoured over Brønsted acids.

## 7. Summary and Future Work

### 7.1 Summary

The mechanism of the deoxofluorination reaction of carbonyl compounds involving SF<sub>4</sub> is not well understood and multiple mechanisms have previously been proposed. The results in this thesis have provided a new outlook on possible reactive intermediates involved in deoxofluorination and have expanded upon previous knowledge of proposed mechanisms.

The Lewis acid-base interactions between SF<sub>4</sub> and the ketones acetone and 2-adamantanone have been explored in the solid state. The [SF<sub>4</sub>·O=C(CH<sub>3</sub>)<sub>2</sub>]<sub>2</sub> and SF<sub>4</sub>·[O=C(CH<sub>3</sub>)<sub>2</sub>]<sub>2</sub> adducts were synthesized and characterized at low temperatures using Raman spectroscopy and, in the case of [SF<sub>4</sub>·O=C(CH<sub>3</sub>)<sub>2</sub>]<sub>2</sub>, single-crystal X-ray diffraction. The X-ray crystal structure of [SF<sub>4</sub>·O=C(CH<sub>3</sub>)<sub>2</sub>]<sub>2</sub> showed weak S---O chalcogen bonding interactions. This was confirmed using Raman spectroscopy where small decreases (< 10 cm<sup>-1</sup>) in the C=O stretching frequencies and large decreases (upwards of 24 cm<sup>-1</sup>) in the axial and equatorial SF<sub>2</sub> stretches of SF<sub>4</sub> were detected. The X-ray crystal structure of SF<sub>4</sub>·(O=C<sub>10</sub>H<sub>14</sub>)·(HF) exhibited a surprising bonding modality where HF bridges a ketone and SF<sub>4</sub>. This structure contrasts with what HF is commonly thought to do in such reactions. It is postulated that HF interacts with SF<sub>4</sub> to abstract a fluoride ion and generate the [SF<sub>3</sub>]<sup>+</sup> cation.

Adducts involving the Lewis acid [SF<sub>3</sub>]<sup>+</sup> with acetone, the simplest aliphatic ketone, cyclopentanone, a cyclic ketone, and 2-adamantanone, a polycyclic ketone, were explored in solutions using <sup>19</sup>F and <sup>1</sup>H NMR spectroscopy at low temperatures. It was found that the [SF<sub>3</sub>·(O=R)<sub>x</sub>]<sup>+</sup> (R = C(CH<sub>3</sub>)<sub>2</sub>, C<sub>5</sub>H<sub>8</sub>, C<sub>10</sub>H<sub>14</sub>; x = 1 or 2) adducts exist below -40 °C. In

the reaction where  $[\text{SF}_3][\text{AsF}_6]$  was mixed with an excess of acetone, the proposed  $[\text{SF}_3 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_3]^+$  cation was observed, as evidenced by the dramatic change in chemical shift (18.43 ppm) compared to non-adducted  $[\text{SF}_3]^+$  (32.91 ppm). In the reactions where one equivalent of ketone reacted with  $[\text{SF}_3][\text{AsF}_6]$ , it was found that  $\text{AsF}_5 \cdot \text{O}=\text{R}$  ( $\text{R} = \text{C}(\text{CH}_3)_2$ ,  $\text{C}_5\text{H}_8$ ,  $\text{C}_{10}\text{H}_{14}$ ) adducts were significant by-products. Above  $-40^\circ\text{C}$ ,  $\text{SF}_4$  formation was observed for each of the reactions. The integration of the  $^{19}\text{F}$  resonances of  $\text{SF}_4$  versus  $[\text{AsF}_6]^-$  is consistent with a proposed dismutation reaction where a highly reactive, elusive  $[\text{SF}_2]^{2+}$  cationic species is formed. The nature of the cationic species present in solution after warming these reactions could not be identified, however, the change in colour to a dark red or orange/brown solution that accompanied the  $\text{SF}_4$  formation may be indicative of a radical cation which is not observable using NMR spectroscopy.

The reactions of  $[\text{SF}_3][\text{AsF}_6]$  with ketones in different solvents led to the discovery of the superacidic medium  $[\text{SF}_3][\text{AsF}_6]/\text{aHF}$  which, consequently, resulted in protonation of the ketones. Superacidic media have long been used to synthesize and stabilize highly reactive species, such as the oxonium cation  $[\text{HO}=\text{R}]^+$ , however, many of these studies are limited to the solution state. In addition, one of the proposed deoxofluorination mechanisms invokes an intermediate which involves HF polarizing the  $\text{C}=\text{O}$  bond allowing for nucleophilic attack of a fluoride. The synthesis of the protonated ketones  $[\text{HO}=\text{C}_{10}\text{H}_{14}]^+$ ,  $[\text{HO}=\text{C}_5\text{H}_8]^+$ , and  $[\text{HO}=\text{C}(\text{CH}_3)_2]^+$ , as well as, the protonated aldehydes  $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2]^+$ ,  $[\text{HO}=\text{CHCH}_3]^+$ , and  $[\text{H}(\text{O}=\text{CHCH}_3)_2]^+$  was carried out and these compounds were characterized in the solid state for the first time. The X-ray crystal structure of the hemiprotonated acetone cation was obtained for the first time, as shown in the complex salt of  $[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_2]_3[\text{HO}=\text{C}(\text{CH}_3)_2]_3[\text{SbF}_6]_5\text{F}$ .

The  $\text{AsF}_5 \cdot \text{O}=\text{R}$  adducts, by-products in the deoxofluorination reactions of  $[\text{SF}_3][\text{AsF}_6]$  with ketones previously discussed, were further studied in targeted reactions to better understand the Lewis acid-base interactions between  $\text{AsF}_5$  and ketones. Lewis acids are frequently used as catalysts in organic reactions and the mechanism is well understood. However, there have been no systematic studies examining the interactions of a Lewis acid with ketones in the solid state. The  $\text{AsF}_5 \cdot \text{O}=\text{R}$  ( $\text{R} = \text{C}(\text{CH}_3)_2$ ,  $\text{C}_5\text{H}_8$ ,  $\text{C}_{10}\text{H}_{14}$ ) adducts have now been synthesized and characterized in the solution and solid states using low-temperature NMR and Raman spectroscopies. The  $^{19}\text{F}$  NMR spectra showed the  $\text{AsF}_5 \cdot \text{O}=\text{R}$  adducts adopting pseudo octahedral geometries about the  $^{75}\text{As}$  nucleus allowing for the observation of two resonances for the axial and equatorial fluorine environments about As. Raman spectroscopy showed characteristic bands of the ketones being shifted upon adduct formation.

Density functional theory calculations were used to optimize the gas-phase geometries of the  $[\text{SF}_3 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_x]^+$  ( $x = 1-3$ ) cations and previously proposed reaction intermediates of deoxofluorination. The gas-phase geometries were also optimized for the  $\text{AsF}_5 \cdot \text{O}=\text{R}$  ( $\text{R} = \text{C}(\text{CH}_3)_2$ ,  $\text{C}_5\text{H}_8$ ,  $\text{C}_{10}\text{H}_{14}$ ) adducts and protonated ketones ( $[\text{HO}=\text{C}_{10}\text{H}_{14}]^+$ ,  $[\text{HO}=\text{C}_5\text{H}_8]^+$ ,  $[\text{HO}=\text{C}(\text{CH}_3)_2]^+$ ,  $[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_2]^+$ ), and aldehydes ( $[\text{H}(\text{O}=\text{CHC}_6\text{H}_5)_2]^+$ ,  $[\text{HO}=\text{CHCH}_3]^+$ ,  $[\text{H}(\text{O}=\text{CHCH}_3)_2]^+$ ) and compared with the X-ray crystal structures, where applicable. NBO analyses of the  $\text{AsF}_5 \cdot \text{O}=\text{R}$  ( $\text{R} = \text{C}(\text{CH}_3)_2$ ,  $\text{C}_5\text{H}_8$ ,  $\text{C}_{10}\text{H}_{14}$ ) adducts, monoprotinated  $[\text{HO}=\text{R}]^+$  ( $\text{R} = \text{C}(\text{CH}_3)_2$ ,  $\text{C}_5\text{H}_8$ ,  $\text{C}_{10}\text{H}_{14}$ ) cations, and hemiprotinated  $[\text{H}(\text{O}=\text{R})_2]^+$  ( $\text{R} = \text{CHC}_6\text{H}_5$ ,  $\text{C}(\text{CH}_3)_2$ ,  $\text{CHCH}_3$ ) cations were carried out. When a Lewis acid (i.e.,  $\text{AsF}_5$ ) or Brønsted acid (i.e.,  $[\text{H}]^+$ ) is bonded to the oxygen of the carbonyl group, the charge of the carbon of the carbonyl group increases, and the  $\text{C}=\text{O}$  bond order decreases due to electron density being withdrawn from the  $\text{C}=\text{O}$  group.

The HOMO and LUMO energies were also calculated for the  $\text{AsF}_5 \cdot \text{O}=\text{R}$ ,  $[\text{HO}=\text{R}]^+$ ,  $[\text{H}(\text{O}=\text{R})_2]^+$ , and  $[\text{SF}_3 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_x]^+$  ( $x = 1-3$ ) compounds. Using acetone as a model system, the LUMO energies can be compared (Table 7.1). Since  $[\text{SF}_3]^+$  is more electrophilic than  $\text{AsF}_5$  and  $[\text{H}]^+$ , the  $[\text{SF}_3 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_x]^+$  ( $x = 1-3$ ) compounds showed the largest decrease in the LUMO energy. The  $\text{AsF}_5 \cdot \text{O}=\text{C}(\text{CH}_3)_2$  adduct ( $-259$  kJ/mol) had a larger decrease in energy from acetone ( $-18$  kJ/mol) compared to that of  $[\text{HO}=\text{C}(\text{CH}_3)_2]^+$  ( $-189$  kJ/mol). These values correlate well with the observed reactivity and stability for each of the systems studied.

Table 7.1 Calculated Energies (kJ/mol) of the HOMO and LUMO for Acetone,  $[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_x]^+$  ( $x = 1, 2$ ),  $\text{AsF}_5 \cdot \text{O}=\text{C}(\text{CH}_3)_2$ , and  $[\text{SF}_3 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_x]^+$  ( $x = 1-3$ ).

Compound	HOMO Energy	LUMO Energy
$\text{O}=\text{C}(\text{CH}_3)_2$	-162	-18
$[\text{HO}=\text{C}(\text{CH}_3)_2]^+$	-376	-189
$[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_2]^+$	-1203	-596
$\text{AsF}_5 \cdot \text{O}=\text{C}(\text{CH}_3)_2$	-933	-259
$[\text{SF}_3 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_3]^+$	-1035	-500
$[\text{SF}_3 \cdot \{\text{O}=\text{C}(\text{CH}_3)_2\}_2]^+$	-1126	-613
$[\text{SF}_3 \cdot \text{O}=\text{C}(\text{CH}_3)_2]^+$	-1271	-732

## 7.2 Directions for Future Work

The reactions involving  $[\text{SF}_3][\text{AsF}_6]$  with various ketones has shed some light on possible reactive intermediates involved in deoxofluorination. The nature of the sulfur species, as well as the cation, in these reactions above  $-40$  °C is still not known and should be further investigated. The use of electron paramagnetic resonance (EPR) spectroscopy could provide valuable information about possible radical species present in solution. As

well, reproducing these low-temperature NMR spectroscopy studies with varying stoichiometries and different solvents (i.e.,  $\text{CH}_2\text{Cl}_2$ ) aid in characterizing the unknown contents produced in these reactions. Whereas, the  $[\text{SF}_3]^+$  salts are insoluble in solvents such as  $\text{CH}_2\text{Cl}_2$ , salts with complex cations, i.e., cationic adducts, have been observed to exhibit solubility in such solvents. The characterization of the elusive  $[\text{SF}_2]^{2+}$  cation should be attempted, which will likely require the use of a stronger base. The  $[\text{SF}_3][\text{AsF}_6]$  salt has proven to be highly reactive towards ketones, even at low temperatures. Reactions utilizing reagents such as Fluolead or DAST might provide a better means to further understanding the interactions of the  $\text{SF}_3$  moiety with ketones.

The synthesis and characterization of other hemiprotonated cations should be further explored. The X-ray crystal structure of  $[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_2]_3[\text{HO}=\text{C}(\text{CH}_3)_2]_3[\text{SbF}_6]_5\text{F}$  has shown that hemiprotonated acetone is an isolated cation, unlike the monoprotonated species which contains contacts with the anion. Attempting to further explore the interactions of  $[\text{HO}=\text{C}(\text{CH}_3)_2]^+$  with a fluoride anion, similar to the moiety in the X-ray crystal structure of  $[\text{H}\{\text{O}=\text{C}(\text{CH}_3)_2\}_2]_3[\text{HO}=\text{C}(\text{CH}_3)_2]_3[\text{SbF}_6]_5\text{F}$ , would provide more information about the interaction modalities of these oxonium cations towards Lewis bases. It may also be beneficial to expand the scope of these protonated carbonyl systems to include diketones (i.e., diacetyl) which may lead to the synthesis of novel dicationic compounds.

					54(0)[0]	

<sup>a</sup> The abbreviations denote stretch ( $\nu$ ), bend ( $\delta$ ), twist ( $\tau$ ), wagging ( $\omega$ ), rock ( $\rho_r$ ), scissoring (sciss), in-plane (i.p.), out-of-plane (o.o.p.), equatorial (eq), and axial (ax). The symmetry species of the modes of free  $\text{AsF}_5$  ( $C_{4v}$  symmetry) is given in parentheses. <sup>b</sup> The Raman spectrum was recorded in a 5-mm glass NMR tube at  $-100^\circ\text{C}$ . <sup>c</sup> Calculations done at the B3LYP/aug-cc-pVTZ level of theory. Unscaled Raman intensities, in  $\text{\AA}^4 \text{u}^{-1}$ , are given in parentheses; infrared intensities, in  $\text{km mol}^{-1}$ , are given in square brackets. <sup>d</sup> The Raman spectrum was recorded in a 1/4-in. FEP tube at  $-100^\circ\text{C}$ . Signals from the FEP sample tube were observed at 1509(2), 1309(4), 1218(3), 751(3), 733(23), 579sh, 294(8)  $\text{cm}^{-1}$ . Artifacts from the laser were observed at 84  $\text{cm}^{-1}$ . <sup>e</sup> Overlap with FEP band. <sup>f</sup> Calculations done at the B3LYP/cc-pVTZ level of theory.

Table A.3.6 Observed and Calculated (B3LYP/aug-cc-pVTZ) Frequencies for Acetone ( $\text{O}=\text{C}(\text{CH}_3)_2$ ) and  $\text{AsF}_5 \cdot \text{O}=\text{C}(\text{CH}_3)_2$ .
